The author of this group having instigated the anatomical-morphological elaboration of the imagines in this volume, this method has proved most instructive in the *Limacodidae*. Quite a number of externally very similar individuals have already been ascertained to be different species, and this cognition will probably increase in future, so that the following elaboration of the author who we are sorry to inform our readers has died in the meantime will have to undergo various changes.

★

Limacodidae.

By H. G. DYAR †.

The name of *Limacodidae* founded upon the genus *Limacodes* Latr. may be adhered to in spite of the fact that *Limacodes* is synonymous with *Apoda* Haw. It is neither of great consequence that *Limacodes* is not at all the oldest generic name of the family, but *Heterogenea* Knoch; we therefore do not hesitate to keep up this name according to the proceeding in the volumes dealing with the other faunae.

There are two groups easily discernible by their larvae though not by their imagines. The first group comprehends larvae of a rather smooth type without horns or thorns. This group occurs throughout Northern Europe, Asia and America; certain species extend also somewhat more to the south, reaching Florida and Texas in America, whereas they do not occur at all in the Tropics, especially in South America. Although a considerable number of genera occur endemically in America, they do not deviate much structurally from the palaearctic prototype, neither as imagines nor as larvae. The latter from this group are normally armed with fleshy horns bearing stinging thorns, though single species and genera also deviate from this type. The early stages are known of but very few American *Limacodidae*.

The oldest Limacodid genus is *Heterogenea* Knoch (1783), as we mentioned above. Some time later (in 1809) *Apoda* Haw. was established, and only in 1825 *Limacodes* Latr. Further genera were only denominated in 1855 and later since the works by FRANCIS WALKER and HERRICH-SCHAEFFER.

Section I. Forewing with an open forked discal vein the branches of which form part of the cell-end; ♂ antennae plain. Distributed in the northern temperate zone.

1. Genus: **Heterogenea** Knoch.

The genus represented also in the palaearctic region differs from the other genera of this section in the absence of the middle spurs of the hind tibiae. Only two species in America.

H. shurtleffii Pack. (164 c) is a small species, the ♂ with black hindwings and black dusted forewings *shurtleffii*, with an indistinct marking shaped like a dog's head. The ♀ exhibits an even less distinct marking on the lustrous yellowish-brown forewing, while the hindwing is blackish. Expanse of wings: ♂ 10—12, ♀ 11—14 mm. Larva green with 2 yellow stripes which are connected by a red spot in the middle. Edge of frons smooth, with a yellow line. On oak and *Ostrya*. New Hampshire, Massachusetts, New York, District of Columbia.

H. minuta Reak. (164 c) is also small, both sexes of the same colouring, the forewing lustrous brownish *minuta*, yellow without any marking; hindwing blackish brown. Expanse of wings: ♂ 10.6, ♀ 11.5 mm. Larva green. 2 red lines intersecting in the middle; edge of frons with 2 horn-points, yellow. It lives on oak. Pennsylvania. The types got into the hands of H. STRECKER who, by mistake, destroyed them as an undesired material. At present not one specimen of this species exists in collections, nor has anybody seen the larva in the last 40 years. REAKIRT mentions 3 spurs on the hind tibiae of the imago. This is surely a mistake; I presume there are two; if there were 4, the species would have to be placed to *Tortricidia* Pack. with *Kronaea* Reak. as a synonym.

2. Genus: **Tortricidia** Pack.

Distinguished from the preceding genus by the presence of 2 pairs of spurs on the hind tibiae, from the following genera by short palpi barely reaching the vertex and a somewhat more projecting head, moreover by a longer and more pointed shape of the wings. Apex of forewing rounded.

T. flexuosa Grt. (164 c). Forewing from dull ochreous to brownish, with most variable markings, with *flexuosa*, a more or less distinct straight median line and a very convex exterior transverse line, more or less shaded with brown. If the latter forms a distinct dog's head marking, it is the form: — **caesonia** Grt. (164 c). Expanse *caesonia*, of wings: ♂ 14—18, ♀ 20—22 mm. The green larva is densely set with cavities, with 2 indistinctly shaded yellow lines, between them more or less red from a tiny spot to a broad band. It lives on oak. New York, Indiana, Virginia, North Carolina.

T. pallida H.-Schäff. (164 c). Forewing brownish ochreous with a silky gloss, with irregular almost *pallida*, quite absent transverse lines. — **flavula** H.-S. shows more distinct linear markings. Expanse of wings: *flavula*, ♂ 10—15, ♀ 16—20 mm. The green larva is flattened with an irregularly shaped red meso-dorsal marking which may be very extensive. In late autumn on various trees and shrubs. Massachusetts, New York, Maryland, Virginia, North Carolina.

T. testacea Pack. (164 c) has silky lustreous brownish ochreous wings with brown-striped veins; the *testacea*, easternmore form *testacea* exhibits an oblique brown shadow in the centre of the forewing, which is absent in the western form — **crypta** Dyar. Expanse of wings: ♂ 14—16, ♀ 20—24 mm. Larva green, flattened with *crypta*, a small irregular red cross on the dorsum. It lives in spring on various trees and shrubs. New Hampshire, New York, Maryland; Manitoba, British Columbia, Colorado.

3. Genus: **Slossonella** Dyar.

This genus containing but one species is characterized by the very short palpi not reaching the vertex and by the very small retracted head.

S. tenebrosa Dyar. Only the ♀ is known so far. Forewing dark brown with the usual blackish lines *tenebrosa*, of a dog's head shape, which, however, are only traceable. Hindwing black, fringe light. Expanse of wings: 18 mm.

4. Genus: **Lithacodes** Pack.

Mostly also small species characterized by the presence of two pairs of spurs on the hind tibiae and by somewhat longer palpi slightly projecting beyond the vertex.

L. fasciola H.-Schäff. (= *divergens* Wkr., *belfragei* Dyar). Forewing yellowish brown, with a white *fasciola*, transverse line which is widened in the middle somewhat like a spot and is provided with a tiny dent below it, with a purple brown shadow behind it; a fine blackish and bent exterior line. Hindwing more or less densely dusted with black. — **laticlavata** Clem. lacks the purple brown shadow behind the white line. Expanse of *laticlavata*, wings: ♂ 14—20, ♀ 20—22 mm. Larva green, stout and broadly rounded, ending quadrangular behind, indistinctly marked yellowish. It lives on many trees and shrubs. New York, Maryland, Virginia, North Carolina, Florida, Mississippi, Texas.

gracea. **L. gracea** Dyar has more pinkish brown forewings with a narrow straight white median line, with a purple shadow behind it: faint traces of a bent exterior line. Hindwing yellowish pink. ♀ still unknown. Expanse of wings: 15—17 mm. From Florida (Paradise Key).

fiskeana. **L. fiskeana** Dyar (164 c) has brown forewings, quite monotonous, with 2 blackish transverse lines, the middle one straight, edged whitish inwards, the exterior one bent; hindwing blackish. Expanse of wings: ♂ 10—12, ♀ 14—16 mm. The green larva ends quadrangular behind, it exhibits a yellow undulate subdorsal line on each side, the parts pressed in are marked yellow. It lives on many shrubs. New Hampshire, Connecticut, Iowa, New Carolina.

graeffii. **L. graeffii** Pack. (164 c) has also monotonously brown forewings with the same linear marking as in *fiskeana*, but the hindwings are brownish yellow, sometimes feebly dusted blackish. Expanse of wings: ♂ 10 to 11 mm; ♀ still unknown. The species may not differ specifically from *fiskeana*, but it is somewhat smaller with light hindwings. Texas.

5. Genus: **Apoda** Haw.

Similar to the genus *Tortricidia*, but the more quadrangular forewing has an almost rectangular apex and a straight costal margin. The names: *Cochlidion* Hbn., *Chelonias* Hbn., and *Limacodes* Latr. are synonymous.

y-inversa. **A. y-inversa** Pack. (164 c). Forewing brownish yellow with 2 parallel dark brown lines, the exterior one straight, shortened by an oblique bent apical line; the veins in the median area are sometimes striped brown. Expanse of wings: ♂ 23—25, ♀ 25—31 mm. Larva of an elliptic shape, green with yellow subdorsal lines uniting at the quadrangular anal end; frons with a yellow transverse line. On hickorey. New York, Pennsylvania, Maryland, North Carolina, Missouri, Texas, Florida. — **parallela** H. Edw. has a more irregularly bent exterior line.

biguttata. **A. biguttata** Pack. (= *tetraspilaris* Wkr.) (164 d). The brown forewing is dusted whitish in the median area between the transverse lines which are edged with whitish; a dark red-brown spot at the apex and anal angle. Expanse of wings: ♂ 20—23, ♀ 24—27 mm. Larva elliptical, quadrangularly cut off behind, whitish green with a narrow whitish subdorsal line on each side. On oaks. New Hampshire, New York, Maryland, North Carolina, Missouri.

rectilinea. **A. rectilinea** G. & R. (164 d) is smaller than the preceding species, the red-brown spots at the apex and tornus of the same colour as the basal area. Median area dusted blackish between the transverse lines, the interior line bordered with white outside. Hindwing black, fringe brown. Expanse of wings: ♂ 17 mm; ♀ still unknown. New Jersey, South Carolina, Florida.

latomia. **A. latomia** Harr. Forewing brown, apex similarly coloured, the median area lighter, inwardly bordered by the whitish-edged median line and an oblique apical line. Hindwing brownish straw-coloured. Expanse of wings: ♂ 15—23, ♀ 26 mm. Eastern Texas.

maxima. **A. maxima** Dyar is much larger than the preceding species, from brownish ochreous to reddish brown, the marginal area occasionally lighter, the centre traversed by a somewhat oblique dark line bordered with white outside. Hindwing somewhat lighter than forewing. Expanse of wings: ♂ 27, ♀ 28 mm. Larva not known. Texas (Brewster County).

6. Genus: **Packardia** G. & R.

Separated from the preceding genus only by the broader and rounder shape of the wings. *Crytosia* Pack. (nec Perr.) is synonymous.

elegans. **P. elegans** Pack. (= *nigripunctata* Goodell) (164 d). Forewing from whitish straw-colour to greyish brown with two whitish transverse lines, the exterior line cut off by an oblique apical streak, a darker shadow behind the interior line, and 2 or 3 black dots above the anal angle. Hindwing lighter or slightly dusted blackish. Expanse of wings: ♂ 15—18, ♀ 18—20 mm. Larva elliptical with a pointed anal end, yellowish green, with an undulate, indistinct, yellowish subdorsal line. It lives on various low trees and shrubs in shady forests. Massachusetts, New York. — **fusca** Pack. are darker specimens.

ceanothi. **P. ceanothi** Dyar has more orange ochreous forewings, the lines as in *elegans*, but rather indistinct, the middle line bordered with dark outside, 2 more or less distinct dark dots above the anal angle. Expanse of wings: ♂ 15—16, ♀ 19—20 mm. Larva similar to that of *elegans*, on low bushes of *Ceanothus*. North Carolina.

geminata. **P. geminata** Pack. (164 d). The chalky white forewing is strewn with brown and has brown lines, the interior one fine, the exterior one parting the apex extends to 2 white dots at the anal angle: the discal

area is often darkened brown or yellowish. Hindwing similarly coloured with a fine border-line and light fringe. Expanse of wings: ♂ 15—24, ♀ 22—23 mm. The elliptically shaped larva has a broad flat dorsal area and terminates behind in a pointed tail, whitish green, the flat area darker, with a white subdorsal line on each side. On many low bushes such as bilberry etc. New Hampshire, Massachusetts, New York, Ohio, Illinois.

P. albipunctata Pack. (= *ocellata* Grt., *goodellii* Grt.). The chalky white ground of the forewing is densely strewn with blackish brown, especially in the ♂; lines as in *geminata*, more or less intensely shaded with dark brown; the ♂ shows the dusting extended almost over the whole surface except the apex. Hindwing blackish, fringe lighter. Expanse of wings: ♂ 20, ♀ 23 mm. The larva seems not to differ from that of *geminata*. On various low bushes. New Hampshire, New York.

Section II. Forewing with a closed forked discal vein, but the one branch is usually more or less rudimentary; if this be very pronounced, the structure resembles Section I: ♂ antennae mostly pectinated. Tropical and temperate zones.

7. Genus: **Sibine** H.-Schäff.

This very difficult genus contains a great number of species which, similar to the Megalopygid genus *Norape* (p. 1084), can partly only be distinguished by the genital apparatus, whilst all of them have a rather similar exterior. Characterized by the slightly curved inner margin of the forewing and rather long palpi. Forewing with the usual 12 veins; hind tibiae with the two pairs of spurs; ♂ antennae pectinated in the basal halves, serrate or plain apically. Synonyma of the genus: *Nyssia* Wkr., *Empretia* Clem., *Eupalia* Wkr., *Streblota* Berg nec Hbn., *Neomiresa* Btlr., *Episibine* Dyar. The following key will facilitate the determination.

Synopsis of species.

1. Hindwing of ♂ more or less triangular, distal margin more or less concave 2
- Hindwing of ♂ rounded 8
2. Hindwing distinctly triangular, disc hyaline 3
- Hindwing dark, the disc somewhat whitish at most 4
3. Hindwing of ♂ with a concave distal margin *intensa* Dyar.
- Hindwing with a straight, not concave, distal margin *aurumacula* Schaus.
4. Hindwing of ♂ quite blackish brown or red 5
- Hindwing of ♂ whitish in the disc 7
5. Hindwing of ♂ straight at the distal margin 6
- Hindwing of ♂ somewhat convex at the distal margin *berthans* Dyar.
6. Forewing dark brown *zellans* Dyar.
- Forewing red with a blackish longitudinal ray *quadrattilla* D. & Hch.
7. Forewing of ♂ with large yellow spots *sibinides* Dyar.
- These spots small *barbara* Dyar.
8. Forewing mixed with light reddish brown 9
- Forewing monotonously light or dark brown 16
9. Ground-colour of forewing lighter than the markings 10
- Ground-colour of forewing darker than the markings 14
10. Forewing with a bent dark stripe from the base to the tornus; the area below it lighter red *rollans* Dyar.
- Blackish shading along the median vein and the veins 11
11. Subapical dots distinct *rufescens* (*megasomoides* Wkr.)
- Subapical dots very indistinct 12
12. Forewing of ♂ dark brown, the black markings not contrasting *rufescens* Wkr.
- Forewing of ♂ lighter brown, the dark markings contrasting 13
- Similar, but only with traces of dark markings *subalbicans* D. & Hch.
13. Aedoeagus short and broad *rufescens* (*determinata* Wkr.)
- Aedoeagus slender and thin *didactica* Dyar.
14. Dark brown, glossy, narrow wings with distinct subapical and sub-basal dots *hyperoche* Dogn.
- Broader lighter brown wings, the marking faded 15
15. Larger, the submedian and apical orange spots distinct, subapical dots large, more or less confluent *lophostigma* Dogn.
- Smaller, orange spot faded, subapical dots small *laurans* Dyar.

16. Forewing dark, glossy, a continuous silver line from the centre of the inner margin to the costal margin before the apex *nesea* Stoll.
Forewing without the silver line 17
17. Forewing with a pointed apex 25
Forewing of ♂ quadrangular, with an obtusely rounded apex 18
18. Forewing glossy, glistening, the dark parts contrasting 19
Forewing less glossy, the darker areas not contrasting 20
19. Larger; hindwing dark, with rough scales between the veins *violans* Dyar.
Smaller; hindwing of ♂ light *bonaërens* Berg.
20. Ground-colour throughout of a warm red tint 21
Less red, with predominating purple grey tints 22
21. Forewing of a glaring dark red-brown colour, with intense yellow sub-basal and subapical dots *apicalis* Dyar.
Forewing dull dark brown, dots absent or indistinct *gertrudans* Dyar.
Similar, but with intense yellow dots *permessa* D. & Hch.
Similar, the subapical dots forming a narrow line *sabis* D. & Hch.
Small, forewing light purple, without dots *pauper* Dyar.
22. Large, stout, with broad wings 23
Small, with narrow wings 24
23. The emarginated end of the ♂ aedoeagus plain, without differentiated tips *francescans* Dyar.
Each of the tips provided with a thorn *eucleides* Dyar.
24. ♂ penis without thorns *stimulea* Clem.
♂ penis with fine furred spines *sarans* Dyar.
25. Hindwing on the average contrastingly whitish in fresh specimens 26
Hindwing not whitish, at least in a series of fresh specimens 29
26. Large, wings rather broad, with distinct yellow dots *priscillans* Dyar.
Of medium size, wings narrow, no dots 27
27. ♂ genitals: anellus with a horn on each side *clarans* Dyar.
Anellus not armed 28
28. Spines of penis in one line, the basal ones small, those in the middle very large, small towards the end *tontineans* Dyar.
Penis with a dense parcel of small spines *dorans* Dyar.
Penis with a parcel of very long slender spines *giseldans* Dyar.
29. Forewing pointed, apex concave costally, prolonged 30
Forewing less sharply pointed 31
30. ♂ wings with large dots, expanse of wings: 47 mm, ♀ with a concave apex *trimacula* Sepp.
♂ forewing without or with reduced dots, expanse of wings: 35—40 mm; ♀ with a less concave apex *horrida* Dyar.
31. ♂ hypopygium: anellus with a dorsal tongue 32
Anellus without a dorsal tongue 37
32. Spines of penis very numerous at the end 33
Spines not increasing in number towards the end 34
33. Spines of penis equally numerous, long and equally long *ximenans* Dyar.
Basally few large spines, numerous small ones towards the end *joyceans* Dyar.
Basally few small spines, numerous large ones at the end *laberia* Dyar.
34. Small (♂: 25—30 mm); forewing purple brown, without markings *helenans* Dyar.
Larger (♂: 33—37 mm); more robust 35
35. Spines of penis very large and scarce, with a series of tiny ones *nitens* Dyar.
The spines short and scarce 36
The spines slender and numerous *iolans* Dyar.
36. Harpe with a uniformly conical end *rufescens* (*pallescent* Dogn.)
Harpe finger-shaped at the end, one side oblique *norans* Dyar.
37. Hindwing dark, forewing pointed, with small reddish subbasal and subapical spots *quellans* Dyar.
Similar, forewing with distinct yellow dots *blanda* Dyar.
Hindwing more or less light, forewing not so pointed, no small reddish spots 38
38. Spines of penis large, as long as the diameter of the aedoeagus *extensa* Schs.
Spines shorter, shorter than the diameter of the aedoeagus 39

39. Spines of penis large, stout, followed by many small ones *reletiva* Dyar.
 Spines fine, slender, no small ones behind them *ophelians* Dyar.

Section I. ♂: anellus with a dorsal chitinous tongue.

S. clarans Dyar. Forewing narrow, oblong, rather pointed; dark red-brown, the veins shaded blackish *clarans*, especially at the base and in the middle; 3 white subapical dots and a small subbasal one. Hindwing pinkish whitish, the veins and a broad inner-marginal area pinkish brown. Expanse of wings: 38 mm. ♀ unknown. Peru.

S. dorans Dyar (164 d). Like *clarans*, somewhat less red-brown, but in fact only discernible by the *dorans*. ♂ hypopygium. Expanse of wings: 35—43 mm. ♀ unknown. Peru, Colombia (Upper Rio Negro), in the Berlin Museum.

S. tontineans Dyar resembles *clarans* and *dorans*, but it is more dark purple without the red-brown *tontineans*. tint except the subbasal part. Hindwing somewhat less pink, greyer, uniformly light. Expanse of wings: ♂ 33—35 mm; ♀ unknown. French Guiana.

S. giseldans Dyar is smaller and more slender than *tontineans*, otherwise the same, but separated by *giseldans*. the genital apparatus (cf. synopsis). Expanse of wings: ♂ 29 mm; ♀ unknown. Brazil (Rio Negro, Amazons).

S. trimacula Sepp (164 d). According to SEPP's figure, the ♂ is large, with narrow long forewings, *trimacula*. dark purple brown with a darker central shadow; the dots yellow, 2 subapical ones and 1 subbasal one. Hindwing light with a pinkish reddish tint and a dark inner-marginal area. The ♀ (if it really belongs to this species) has a distinctly concave apex and a reddish spot here, with reduced yellow spots. Expanse of wings: ♂ 47 mm, ♀ 57—63 mm. I have not seen any ♂. Larva elliptically flattened, with short horns which are absent on the middle segments; grass-green laterally and in a quadrangular frontal spot, the rest of the dorsum yellowish green, the horns purple. The eggs are deposited in a pack: the larvae are at first gregarious, living on orange-trees. Guiana.

S. horrida Dyar (= ? *affinis* Mschlr.) (164 d). Dark purple brown with a silky gloss, wings oblong *horrida*. as in *trimacula*, dots yellow, very small, variably developed. Hindwing dark brown, rarely somewhat lighter, but the inner-marginal area is invariably broad dark. ♀ similar, apex slightly concave costally; both sexes with a darker contrasting area in the cell and at the apex. Hindwing of ♂ often with rough purple scales between the veins. Expanse of wings: ♂ 33—40, ♀ 50—58 mm. Larva unknown. Guatemala, Costa Rica, Panama, Ecuador, Colombia, Venezuela. MÖSCHLER's *affinis*, described according to 1 ♀ from Surinam, cannot be safely determined, though *horrida* is the only species I have at hand with a sufficiently large ♀ to correspond to *affinis*; *horrida* from Surinam, however, I have not at hand.

S. joyceans Dyar (164 e). Forewing triangular, rather short, dark, less red than *horrida*; dots white, *joyceans*. the subapical ones are coherent almost in an oblique line. Hindwing moderately dark, sometimes lighter in the disc, dark in the ♀. Expanse of wings: ♂ 30—33, ♀ 40—43 mm. Larva elliptical, flattened, quite light green down to the sides, with a narrow black line above the lateral horns which are very short, absent in the middle, light, with a black tip and a black basal ring. It lives on *Lansium americanum* and other plants. Panama.

S. laberia sp. n. is similar to *joyceans*, but more robust and with broader wings, though of the same *laberia*. size; separated by the ♂ hypopygium (cf. synopsis). Expanse of wings: ♂ 36 mm, ♀ unknown. Brazil (Rio de Janeiro).

S. rufescens Wkr. (= *determinata* Wkr., *plora* Schs., *pallescens* Dogn.). Wings of normal shape, *rufescens*. moderately long; dark red-brown, generally on a lighter red ground, veins and cellular area shaded black; mostly without any dots, if they are present: — **megasomoides** Wkr., white. Hindwing pinkish brown, light, *megasomoides*. darker at the inner margin. Expanse of wings: ♂ 32—38, ♀ 42—54 mm. Colombia, Venezuela, Brazil (Amazons). DOGNIN's *pallescens* was founded upon a pale much flown ♀. A fresh specimen from the same habitat is dark brown, and other ♂♂ which I range here are also dark.

S. iolans Dyar (? = *modesta* Cr.). Dark red-brown, glossy in a certain exposure to light, with a darker *iolans*. shadow through the cell and submedianly, as in dark forms of *rufescens*, but the ♂ hypopygium is different. Expanse of wings: ♂ 30—40, ♀ 43—45 mm. Larva elliptical, flattened, with very short horns, yellowish

grass-green, with a fine black line between the horns of the 5th segment and behind on the 13th segment; horns dark, the spread out spines on them pink. Brazil; Paraguay.

didactica. **S. didactica** Dyar. The ♂ is small, purple red-brown, still more reddish below the cell, the veins shaded darker, the dots white. Hindwing light. Expanse of wings: ♂ 28 mm; ♀ unknown. From British Guiana. A ♀ which seems to belong to it would correspond to STOLL's figure of *fusca*. Compare also *nitens*.

subalbicans. **S. subalbicans** sp. n. Like *didactica*, but without the broad dark area in the cell of the forewing. Expanse of wings: ♂ 30 mm; ♀ unknown. From Brazil.

nitens. **S. nitens** Dyar (? = *fusca* Stoll) has a more rounded shape of the wings and is more scantily scaled than the preceding 8 species, the veins often contrasting on the semidiaphanous ground; dots white, generally very distinct, but small; hindwing from pinkish brown to dark brown, sometimes with the rough scales of *horrida*; the ♀ with more monotonous hindwings, the subapical dots of the forewing in an oblique line as in the ♂, often somewhat confluent. Expanse of wings: ♂ 27—35, ♀ 45—47 mm. Guiana, Peru, Brazil (Amazons). Another race which I separate as — **alicians** f. n. has lighter, whitish hindwings with a pink inner margin, some are also a little darker. The ♀ is glossy and somewhat transversely striated, without subapical dots. According to 8 ♂♂ and 2 ♀♀ from Brazil, Prata (Amazons), 100 km from Pará (A. H. FASSL).

ximenans. **S. ximenans** Dyar resembles *nitens*, dark purple brown, with very small dots, the hindwings also very dark. The ♂ hypopygium similar to that of *joyceans*, but different in details (cf. synopsis, No. 33). Expanse of wings: 32 mm; ♀ unknown. Brazil (Rio Tocantins).

violans. **S. violans** Dyar is rather large, glossy dark purple brown, darker stripes in the cell and submedianly distinct in a certain exposure to light; dots light yellow, large and somewhat confluent. Hindwing dark red-brown, the ♂ with rough more purple scales between the veins. Expanse of wings: ♂ 33—35, ♀ 48 mm. Colombia.

bonaërensis. **S. bonaërensis** Berg. ♂ with rather obtuse wings, from dark brown to blackish brown, dots reduced or absent. Hindwing moderately dark, sometimes lighter in the disc. The ♀ with more pointed wings with a red apical spot, the dots white, in an oblique line, somewhat confluent. Expanse of wings: ♂ 28—30, ♀ 37 to 52 mm. Larva extremely similar to that of *trimacula*. Argentina, Brazil, Paraguay.

helenans. **S. helenans** Dyar is a small species, smooth, dark purple brown, without any marking. Hindwing light purple brown, darker along the inner margin. Hypopygium as in *bonaërensis*, but the shape of the wings is different. Expanse of wings: ♂ 25—28, ♀ 40—42 mm. Bolivia; Brazil (Amazons), Peru (Rio Putumayo).

priscillans. **S. priscillans** Dyar. Large, light red-brown, with a red apical spot and a subbasal one, with a narrow dark stripe below the cell; a single yellowish subapical dot and a subbasal one, both rather large. Hindwing light yellowish-white, the veins and inner margin broadly dull reddish, base of fringe dark. Expanse of wings: ♂ 43 mm; ♀ unknown. Mexico (Zacualpan).

lophostigma. **S. lophostigma** Dogn. Shape of wings obtuse, purple brown with extensive subapical and subbasal orange tints; dots large, round, yellow. Hindwing rather dark, pinkish brown. Expanse of wings: ♂ 33—36, ♀ 45 mm. French Guiana, Brazil (Amazons).

laurans. **S. laurans** Dyar (164 e) has obtuse wings of a lighter purple brown colour and darker fringes, with a broad orange-red tinge along the inner margin below a darker stripe; subapically no other colour, no dots. Hindwing light purple brown, the inner margin assuming the tinge of the inner margin of the forewing. Expanse of wings: ♂ 28 mm; ♀ unknown. Brazil (São Paulo Olivença, Amazons).

Section II. ♂ anellus without a chitinous dorsal tongue.

extensa. **S. extensa** Schs. (164 e). Large and with pointed wings, dark red-brown with reddish subbasal and subapical spots, a blackish shadow through the cell and below the median vein, a single white dot, often prolonged or also extinct. Hindwing light, sometimes suffused with pinkish brown, with a dark inner margin. Expanse of wings: ♂ 32—40, ♀ 45—64 mm. Larva elliptical, flattened, with very short horns, light green, the horns green. It lives gregariously and also spins the cocoons together in a common web. Mexico, Florida (Paradise Key). This species and perhaps also the following *reletiva* and *ophelians* have larvae of the cross-horny type of the Section I, but the chitinous tongue of the anellus is absent.

reletiva. **S. reletiva** Dyar is smaller than *extensa*, with different spines on the penis, otherwise very similar. Expanse of wings: ♂ 30—35, ♀ 40 mm. San Salvador.

ophelians. **S. ophelians** Dyar has more obtuse wings than *extensa* and less distinct markings, it is more scantily scaled and likewise separable by different spines of the penis. Expanse of wings: ♂ 30—35, ♀ 46—50 mm. Guatemala, Costa Rica, Panama, Colombia.

S. gertrudans Dyar. Wings obtuse, dark umber-brown, with a slight reddish tint, blackish stripes *gertrudans*, through the cell and submedianly, the dots extinct. Hindwing purple brown in various shades. Expanse of wings: ♂ 30—35 mm; ♀ unknown. Mexico.

S. permessa *n. sp.* resembles *gertrudans*, but it has distinct large yellow dots on the forewing. Expanse *permessa*, of wings: ♂ 31 mm; ♀ unknown. Brazil (Minas Geraës).

S. sabis *n. sp.* differs from *permessa* in the subapical dots forming a narrow continuous line. Hind- *sabis*, wing lighter. Expanse of wings: ♂ 30 mm; ♀ unknown. Peru.

S. quellans Dyar. Forewing pointed, glossy dark brown with contrasting areas, subapical and sub- *quellans*, basal reddish spots, without dots. Hindwing rather dark brown. Expanse of wings: ♂ 30 mm; ♀ unknown. Colombia.

S. rollans Dyar. Wings obtuse quadrangular, light pinkish red-brown with a narrow blackish stripe *rollans*, below the cell, the inner-marginal area below it bronze red. Hindwing rather dark reddish brown. Expanse of wings: ♂ 25—27 mm; ♀ unknown. Guiana, Peru, Brazil (Amazons).

S. eucleides Dyar. Wings obtuse, costal and inner margins almost parallel, dark blackish brown with *eucleides*, one subbasal white dot and 3 small subapical ones. Hindwing rather dark purple brown. Expanse of wings: ♂ 32—34 mm; ♀ unknown. Brazil, Paraguay.

S. francescans Dyar resembles *eucleides*, but it is somewhat less dark brown, and the black stripe *francescans*, below the median vein is more distinct. Genital apparatus different (cf. synopsis). Expanse of wings: ♂ 36 mm; ♀ unknown. Bolivia, Colombia (Rio Negro).

S. quadratilla *sp. n.* is allied to the following *zellans*, but of a more mahogany-red ground-colour, the *quadratilla*, forewing with a dark stripe along the median vein as far as the apex the centre of which is grey. Expanse of wings: ♂ 33 mm; ♀ unknown. French Guiana.

S. zellans Dyar. Forewing narrow, pointed; hindwing triangular with a straight distal margin; dark *zellans*, purple brown, without any markings. Hindwing almost as dark as forewing. Expanse of wings: ♂ 37 mm; ♀ unknown. Brazil (Pará).

S. berthans Dyar is like the preceding species, but blacker, with less pointed forewings; the distal *berthans*, margin of the triangular hindwing convex. ♀ less intensely blackish, with a red apical spot and a yellowish subapical stripe. Hindwing lighter brown. Expanse of wings: ♂ 34, ♀ 54 mm. Paraguay.

S. sarans Dyar is a small dark species with obtuse wings, with small white subbasal and subapical *sarans*, dots. Hindwing dark brown. Similar in marking to *stimulea*, but the penis is spined. Expanse of wings: ♂ 23 mm; ♀ unknown. Guatemala.

S. pauper Dyar (164 e). Monotonously very light purple brown; hindwing still lighter, veins and inner *pauper*, margin of a pinkish reddish tint. Expanse of wings: ♂ 21—28 mm; ♀ unknown. Mexico.

S. nesea Stoll (= *vidua* Sepp, *fumosa* Wkr.) (164 e). Forewing glossy, very dark brown, with a silvery *nesea*, shine at the inner margin towards the anal angle, a narrow subapical silver streak, and subbasally with silvery dentate lines which are quite indistinctly connected. Hindwing much lighter brown, darker at the inner margin. Expanse of wings: ♂ 35—40, ♀ 52 mm. Larva elliptical, flattened, the anterior and posterior subdorsal horns long, the lateral ones rather long, too; light green, the horns purple, a quadrangular grass-green spot in the centre of the dorsum is framed by a yellow quadrangle. Guatemala, Costa Rica, Panama, Colombia, Venezuela, Guiana, Peru, Brazil (Amazons).

S. stimulea Clem (164 f). Dark red-brown, glossy, the discal and submedian areas shaded blackish; *stimulea*, the subbasal and subapical dots white, rather large, the latter in one line, confluent in the ♀. Hindwing dark brown. Expanse of wings: ♂ 20—26, ♀ 28—38 mm. Larva elliptical, arched, the subdorsal horns on the 5th and 11th segments long, the others short; purple brown with a large bright green spot in the centre of the dorsum, extending laterally down to below the horns of the 11th segment and enclosing a purple spot dorsally, all of them edged with white; one yellow dorsal spot each between the horns of the 5th and 11th segments, two larger spots behind them. It lives on many shrubs and trees. Massachusetts, New York, Maryland, Virginia, Florida. — A form differing neither in the colouring nor in the genital apparatus, but which may nevertheless be a good species, occurs in Paraguay (1896, HEYNE, Dognin Coll.), and a red form, probably also from Tropical America, is newly described (Zoolog. Museum, Berlin) as — **ausa** *n. f.* *ausa*.

S. apicalis Dyar (164 f) resembles *stimulea*, but it has broader wings, the hindwings are lighter brown, *apicalis*, the dots yellow and more extensive, sometimes augmented by a stripe in the cell. Expanse of wings: ♂ 25 to 35, ♀ 35—50 mm. Mexico, Guatemala, Costa Rica.

- hyperoche*. **S. hyperoche** Dogn. looks like *apicalis*, but it shows yellowish-brown subbasal and subapical spots which are more or less strongly developed. Expanse of wings: ♂ 23—33, ♀ 30—40 mm. Larva exactly like that of *stimulea*. Panama, Colombia, Ecuador.
- intensa*. **S. intensa** Dyar. ♂ forewing narrow and pointed. Hindwing triangular with a concave distal margin and a hyaline disc; colouring like that of *apicalis*, the dots more extensive, yellow, inclined to lie in a bent line. ♀ with a more oblique distal margin, the middle one of the subapical dots projecting a little. Expanse of wings: ♂ 23—30, ♀ 37—45 mm. Guiana, Brazil.
- auromacula*. **S. auromacula** Schs. differs from *intensa* in its less narrow wings of the ♂, and the straight not concave distal margin of the hindwing. Expanse of wings: ♂ 31, ♀ 34—48 mm. Venezuela.
- barbara*. **S. barbara** Dyar. Wings pointed, hindwing of ♂ with a straight distal margin; dark purple brown with a red apical spot, with another submedian one behind the subbasal dots; dots light yellow, the subapical ones united S-like. Hindwing dark brown, the disc of the ♂ whitish. Expanse of wings: ♂ 33, ♀ 44 mm. Brazil (Rio de Janeiro, Sao Paulo).
- sibinides*. **S. sibinides** Dyar differs from *barbara* in its larger dots, the subapical ones of which are not united S-like. Hindwing pink at the costal margin, light in the disc, broadly dark brown at the inner margin. Expanse of wings: ♂ 34 mm; ♀ unknown. Brazil (Pernambuco).
- blanda*. **S. blanda** sp. n. Forewing as in *sibinides*, but the hindwing rounded as in *barbara*. Expanse of wings: ♂ 31—34 mm; ♀ unknown. Brazil (Minas Geraes, Rio de Janeiro, Sao Paulo).

S. Genus: **Parasa** Moore.

This universally distributed genus contains mostly green or brown and green species (cf. Vol. II, p. 345; Vol. X, p. 694; Vol. XIV, p. 462). Hind tibiae spined. Forewing with the usual 12 veins, 10 generally from the cell; palpi projecting beyond the frons; inner margin of forewing straight; ♂ antennae pectinated only in the basal halves. As the distinction of the numerous species is often difficult, we supply again an analytical key so as to facilitate the determination.

Synopsis of species.

1. Forewing of a bright apple-green 2
Forewing brown, with a green band, at least in the ♀ 14
2. With a brown marginal band which is twice inwardly angled (discally and submedianly) 3
The brown marginal band only once inwardly angled 10
3. Hindwing yellow, at least at the costal margin 4
Hindwing brown 7
4. Margin of forewing narrow, hindwing yellow as far as the margin *herbina* Schs.
Margin of forewing broad 5
5. Large; hindwing yellow almost to the margin *viridiplena* Wkr.
Small; hindwing less yellow 6
6. The brown margin blackish; hindwing dark excepting the costal margin *cucumenica* Dyar.
The brown margin not blackish; hindwing broadly yellow *loyola* Dyar.
7. Discal dot brown, marked white *campylostagma* Dogn.
Discal dot brown 8
Discal dot green, rather indistinct *imitata* Drc.
8. Margin of forewing broad; discal dot small 9
Margin of forewing narrow; discal dot of medium size *mompha* Dyar.
9. A larger species; wings longer, less rounded, the dark marking red-brown *flora* Dyar.
A smaller species; wings shorter, more rounded, the dark marking greyish black *stiphra* Her. & Hopp.
10. Marginal band with a very long submedian dent from the margin to the cell *macrodonta* Her. & Hopp.
Margin with a short dent 11
11. Hindwing yellow 12
Hindwing brown 13
12. A larger species; discal spot distinct *mossica* Dyar.
Smaller; discal dot small or indistinct *wellesca* Dyar.
13. Margin of forewing very narrow, the dent small; discal dot small, base mixed with yellow *laranda* Drc.
Large, without a discal dot, marginal dent sharp, below the apex *constricta* Her. & Hopp.
Smaller, with a discal dot, marginal dent a broad angle from the apex *laonome* Drc.
14. Forewing with a green band in both sexes 15
Forewing of ♂ without a green band 19

15. Hindwing yellow at the base 16
Hindwing dark, scantily scaled in the disc *maysi* Schs.
16. A larger species with broad wings; the green band broad, a dark mark in the
brown marginal area *indetermina* Bsd.
Smaller, with more pointed wings; the green band narrow, the brown margin
without a mark 17
17. The green band occupies more than a third of the wing and extends at the inner
margin to the base *chloris* H.-S.
The green band is narrower, not reaching the base at the inner margin 18
18. A larger species; the green band broad and uniform *cuernavaca* Dyar.
Smaller, the green band strangulated *minima* Schs.
19. Wings normally shaped, not produced apically 20
Wings of ♂ strongly produced at the apex 22
20. Light brown, hindwing yellow at the base 21
Both wings dark brown, forewing with a whitish distal line *viridogrisea* Dyar.
21. Forewing dark brown at the base, median band lighter brown, margin light *mionexia* Dyar.
Forewing as light at the base as at the margin; central band dark (expanse of
wings: 17 mm) *minuta* Her. & Hopp.
22. Forewing light brown *cebrenis* Schs.
Forewing dark brown, monotonous *schausi* Dyar.

P. herbina Schs. (164 g). Forewing green, the brown distal margin narrow, with two rounded indentions, *herbina*. running along the inner margin as far as the base; hindwing ochreous orange with a narrow brown distal margin. Expanse of wings: ♂ 21 mm; ♀ unknown. Brazil.

P. viridiplena Wkr. (164 g). Forewing bright green in the disc, distal margin rather broadly brown, *viridiplena*. spotted blackish and twice projecting angularly, the base also obliquely cut off brown. Hindwing yellow with a uniformly light brown distal margin. Expanse of wings: ♂ 24—30, ♀ 38 mm. Brazil.

P. cucumenica Dyar (164 h). Forewing dark green, the obliquely cut off basal area and the broad distal *cucumenica*. margin blackish, the latter projecting twice. Hindwing blackish brown, yellowish at the costal margin. Expanse of wings: ♀ 27 mm; ♂ unknown. Brazil.

P. loyola Dyar is smaller than *viridiplena*, the green area relatively narrower. Hindwing yellow in the *loyola*. basal two thirds with a broad brown margin. ♂ unknown. Expanse of wings: ♀ 27—28 mm. Brazil.

P. campylostagma Dogn. Green, base and distal margin narrow, the latter twice indented, with a white *campylo-* dentate discal streak encircled with brown. Hindwing dark brown. Expanse of wings: 25 mm; ♀ unknown. *stagma*. Colombia.

P. imitata Drc. (= fauna Dyar) (164 h) is a large green species with a very narrow brown basal and *imilala*. marginal area and with a darker green discal dot. Hindwing dark brown. Expanse of wings: ♂ 32—35, ♀ 46 mm. Central America, Colombia.

P. mompha Dyar is a slim species with broad wings; forewing bright green, basal area obliquely cut off *mompha*. dark brown, the margin suffused with wood-brown except a spot in the centre; an oval dark discal spot at the cell-end. Hindwing red-brown. ♂ unknown. Expanse of wings: ♀ 35 mm. Peru.

P. flora Dyar (164 h) resembles *mompha*, but it is more strongly built, with straighter margins of the *flora*. wings, the marginal band of the forewing broad. Expanse of wings: ♂ 29—33, ♀ 35 mm. Brazil; French Guiana.

P. stiphra Her. & Hopp is smaller than *flora*, with shorter and more rounded wings, the dark colour *stiphra*. more blackish grey instead of red-brown. Expanse of wings: ♂ and ♀ 25—30 mm. Peru.

P. macrodonta Her. & Hopp. Forewing with a roundedly indented basal area, a broad dark distal margin *macrodonla*. with a long submedian dent extending into the cell and reaching the dark basal colour; a transverse strigiform spot at the cell-end. Hindwing dark brown. Expanse of wings: ♂ 26 mm; ♀ unknown. Peru (Chinchuras).

P. mossica Dyar is rather large, the dark basal and marginal areas reduced, the marginal area broadly *mossica*. indented discally and mixed with lilac, a small dark spot at the cell-end. Hindwing yellow, fringe interspersed with dark scales. Expanse wings: ♂ 33—35 mm; ♀ unknown. Colombia.

P. wellesca Dyar (164 h) is smaller than *mossica*, only a dot at the cell-end. Expanse of wings: ♂ 24 to *wellesca*. 30 mm; ♀ unknown. Costa-Rica.

- laranda*. **P. laranda** Drc. (164 h) has a very narrow distal margin with only a short discal dent; the basal area is also narrow, intermixed with yellow; discal dot dark, mixed with yellow in the ♀. Hindwing dark brown. Expanse of wings: ♂ 30, ♀ 34 mm. Guatemala.
- constricta*. **P. constricta** Her. & Hopp. likewise shows a but narrow brown margin with a long sharp discal dent, without a discal dot (dark green). Hindwing dark brown. Expanse of wings: ♂ 38 mm; ♀ unknown. Panama.
- laonome*. **P. laonome** Drc. (164 h) resembles *laranda*, but it lacks its yellow infiltration in the basal area; marginal area often dusted lilac, with a broad discal dent, narrow below it; a dark discal dot. Expanse of wings: ♂ 25—30, ♀ 33—36 mm. Mexico; Guatemala. DRUCE's figure shows the margin of the forewing roundly expanded submedianly; none of our specimens shows this behaviour, but HERING & HOPP find it to be variable.
- indetermina*. **P. indetermina** Bsd. (= *vernata* Pack.). Forewing bright green, basal and marginal areas wood-brown, without dents, a dark spot in the brown margin of the forewing. Hindwing yellowish, dusted brown at the margin. Expanse of wings: ♂ 22—28, ♀ 24—30 mm. Larva yellow or red, with undulating purple lines on the dorsum and laterally; horns variably long, some long, yellow or bright red, the lateral horns short. It lives on different low shrubs. New York, West Virginia.
- chloris*. **P. chloris** H.-S. (= *viridis* Reak., *fraterna* Grt.) (164 h). Forewing somewhat narrow, triangular; the brown basal area is obliquely cut off, the marginal band broad, wood-brown, with darker striped veins, the green colour reaches the base of the wing. Hindwing yellow in the basal half, distal half brown. Expanse of wings: ♂ 16—22, ♀ 23—25 mm. Larva with a hunch in front, tapering behind into a pointed tail, brown mixed with reddish, all the horns very short and insignificant. On oaks and other foliage-trees. Massachusetts, New York, Maryland, Virginia, North Carolina.
- cuernavaca*. **P. cuernavaca** Dyar (164 i) resembles *chloris*, except the green colour not distinctly reaching to the base of the forewing in the ♂, and the brown colour is darker. Specimens from different habitats vary much in size. Expanse of wings: ♂ 12—22, ♀ 24 mm. Mexico, San Salvador, Costa Rica.
- minima*. **P. minima** Schs. (164 i) has a narrower green band than *cuernavaca*, the dark basal area is broad; darker than the margin. Expanse of wings: ♂ 16—18, ♀ 18 mm. Mexico (Eastern Coast).
- maysi*. **P. maysi** Schs. has more pointed wings than *minima*, the dark areas dark brown. Hindwing blackish, scantily scaled in the disc. Expanse of wings: ♂ 16—18 mm; ♀ unknown. Guatemala.
- viridogrisea*. **P. viridogrisea** Dyar. ♂ dark brown, the wing divided by a light undulating line, the basal half more reddish than the distal half. ♀ with a narrow green band bending towards the base, bordered with reddish outside. Expanse of wings: ♂ 24—28, ♀ 31 mm. Mexico, Guatemala, Costa Rica.
- mionexia*. **P. mionexia** Dyar. Forewing of ♂ dark brown, the base chocolate brown, a median band red-brown, the marginal area lighter brown; hindwing light reddish brown. ♀ with a rather broad green band in the place of the red median band of the ♂. Expanse of wings: 19—22, ♀ 24 mm. Argentina.
- minuta*. **P. minuta** Her. & Hopp differs from *mionexia* in the light brown basal area which is coloured like the marginal area, a darker brown median band bordered by a whitish line on both sides. Expanse of wings: ♂ 17 mm; ♀ unknown. Brazil.
- cebrenis*. **P. cebrenis** Schs. (= *lysia* Drc.) (164 i). Forewing of ♂ broadly red-brown in the middle, the base and marginal area grey, the colours intergrading; hindwing blackish, red-brown along the inner margin. ♀ with a broad shaded green median band, the margin two-coloured, red inside, grey outside. Expanse of wings: ♂ 17—20, ♀ 24—26 mm. Mexico.
- schausi*. **P. schausi** Dyar (164 i). Forewing of ♂ dark red-brown in the middle, the base and margin blackish, the colours not contrasting; hindwing blackish, scantily scaled in the disc. ♀ with a green band bordered with reddish on both sides, the base, margin and hindwing blackish. Expanse of wings: ♂ 20—25, ♀ 30—33 mm. Guatemala, Costa Rica, French Guiana, Peru, Brazil (Amazons).

9. Genus: **Zaparasa** Dyar.

Separated from the preceding genus by the absence of the spurs on the posterior tibiae. Moreover, the forewing shows veins 7 and 8 stalked, 9 absent, 10 arises from the cell. Only two species similar to the preceding genus, but much weaker.

- sylvia*. **Z. sylvia** Dyar (164 i). Forewing light green, the basal half of the costal margin with a round light brown spot crossing the cell; the light brown distal margin is somewhat excavated subcostally, more so medianly. Hindwing yellowish white. Expanse of wings: ♂ 23 mm; ♀ unknown. Mexico.

Z. brueckneri *Her. & Hopp* has brown forewings with two fine green transverse lines, both strongly ex-*brueckneri*. curved in the middle; some green colouring in the cell. Hindwing not marked. Expanse of wings: ♂ 23 mm; ♀ unknown. Guatemala.

10. Genus: **Paraclea** *Dyar*.

Likewise very similar to *Parasa* from which it differs in the antennae being pectinated in the basal two thirds. Only 1 species:

P. pretiosa *Stkr.* (= *dolita* *Schs.*) (164 i). Forewing green with a narrow yellowish straw-coloured margin *pretiosa*. mixed with brown outside and inside. Hindwing pale brownish yellow. Expanse of wings: 20 mm; ♀ unknown. Brazil.

11. Genus: **Euclea** *Hbn.*

A rather large genus of mostly small or very small species. Palpi somewhat stout with a short terminal joint, antennae of ♂ pectinated in the basal halves; posterior tibiae spurred; forewing with all the 12 veins, vein 10 usually stalked with 7—9, forewing with a straight inner margin. The colouring generally contains no red-brown or ochreous tints, often mixed with green, but the thorax is never green. The distinction being partly very difficult we supply an analytical table facilitating the determination. *Metraga* *Wkr.* and *Nochelia* *Clem.* are generic synonyms.

Synopsis of Species.

- | | |
|--|--------------------------------|
| 1. Forewing marked with green (rarely with yellow) | 2 |
| Forewing without green | 14 |
| 2. Forewing with a very large green spot occupying almost the whole wing, indented at the anal angle, here without any red | <i>incisa</i> <i>Harv.</i> |
| The green area smaller, marked red at the indentation with a more or less distinct discal dot | 3 |
| 3. The green area fills up more than the cell; hindwing light. | <i>paenulata</i> <i>Clem.</i> |
| The green area smaller; hindwing dark brown | 4 |
| 4. The green area fills part or the whole of the cell | <i>elliottii</i> <i>Pears.</i> |
| Cellular area without green | 5 |
| 5. Green divided into 2 round spots | <i>nanina</i> <i>Dyar.</i> |
| Green markings angular. | 6 |
| 6. Green markings connected. | <i>viridiclava</i> <i>Wkr.</i> |
| Green in separated spots | 7 |
| 7. The middle green spot developed about as well as the subbasal and subapical ones | 8 |
| The middle spot smaller than the others or absent | 8 |
| 8. The green strongly developed; apex of forewing quadrangular | 9 |
| Green spots small; apex of forewing rounded | 10 |
| 9. A larger species; green spots distinct, almost confluent | <i>cipior</i> <i>Dyar.</i> |
| Smaller, green spots separated | <i>cippus</i> <i>Cr.</i> |
| 10. Brown, hindwing red-brown | <i>norba</i> <i>Drc.</i> |
| Blackish, hindwing chocolate brown | <i>copac</i> <i>Schs.</i> |
| 11. Basal and apical spots connected by a row of dots | <i>interjecta</i> <i>Dyar.</i> |
| Median area absent | 12 |
| 12. Basal spot with a prolongation above | <i>querceti</i> <i>H.-S.</i> |
| Basal spot without a prolongation | 13 |
| 13. Basal spot green | <i>delphinii</i> <i>Bsd.</i> |
| Basal spot yellow | <i>aemilia</i> <i>Stoll.</i> |
| 14. Forewing with a narrow silvery line below the median vein | 15 |
| Forewing without the silvery marking | 38 |
| 15. This silvery line straight | 16 |
| Silvery line undulate or angular | 23 |
| 16. A larger more robust species. | 17 |
| A smaller, slender species | 19 |
| 17. Forewing glossy, without any brown before the white apical dots | 18 |
| Forewing light, dull, a brown spot before the white subapical line | <i>pallicolor</i> <i>Dyar.</i> |

- | | |
|---|----------------------------|
| 18. Forewing dark brown in the disc | <i>agchiatropa</i> Dogn. |
| Forewing without distinct dark spots | <i>peroloides</i> Dogn. |
| 19. Subapical dots united into a line | <i>costilinea</i> Dyar. |
| The dots separated (often all extinct) | 20 |
| 20. Ground-colour of forewing blackish brown. | 21 |
| Ground-colour greyish brown, apically often reddish | <i>determinata</i> Drc. |
| 21. Subbasal silvery line distinct | <i>plugma</i> Sepp. |
| This line extinct | 22 |
| 22. A larger species, expanse of wings: 18 mm | <i>perplexa</i> Wkr. |
| Smaller, expanse of wings: 15 mm | <i>hoboa</i> Schs. |
| 23. A straight fine subapical silvery line | 24 |
| Subapical silvery line broken or extinct | 30 |
| 24. Subbasal line obliquely outward, extending along the median vein to the base | <i>distrakens</i> Dyar. |
| Subbasal line obliquely inward. | 25 |
| 25. Quite light yellow | <i>flava</i> B. & McD. |
| With different dark brown tints | 26 |
| 26. Markings distinct and contrasting | 27 |
| Markings extinct | 29 |
| 27. No distinct discal dot, the ground monotonous | <i>dolliana</i> Dyar. |
| Discal dot present, differently coloured | 28 |
| 28. Subapical line beneath inwardly angled to a light shadow. | <i>diversa</i> Drc. |
| This line distinctly coherent with the light shadow | <i>vericrux</i> Dyar. |
| 29. Hindwing red-brown | <i>poasica</i> Dyar. |
| Hindwing dark chocolate brown | <i>lamora</i> Dogn. |
| 30. Red-brown, no silver subapically, but an oblique subbasal silvery line | <i>spadicis</i> Grossbeck. |
| Variably tinged, subapically at least with traces of silver | 31 |
| 31. Forewing of a blackish ground-colour, disc scantily scaled in both wings | <i>bidiscalis</i> Dyar. |
| Forewing differently tinged with brown or yellow, disc not transparent | 32 |
| 32. A reddish flesh-coloured spot between the subbasal and subapical silver | 33 |
| Without this light spot | 37 |
| 33. Forewing dull olive yellow, discal streaks below the cell continued to marginal spots | <i>immundara</i> Dyar. |
| More speckled; margin not spotted | 34 |
| 34. Ground-colour yellowish, no discal spot | <i>cassida</i> Dyar. |
| Ground-colour red-brown, with a discal spot. | 35 |
| 35. Wings rather scantily scaled, scales somewhat erect, ground-colour lighter | 36 |
| Wings less scantily scaled, ground-colour dark brown | <i>buscki</i> Dyar. |
| 36. From Brazil | <i>ruja</i> Btlr. |
| From Colombia | <i>baranda</i> Schs. |
| From Costa Rica | <i>jelyce</i> Dyar. |
| 37. The subbasal silver mark like a slender lunule with curved ends | <i>trichathdota</i> Dyar. |
| This lunular mark short and thick | <i>cuspostriga</i> Dyar. |
| 38. Monotonously dark brown; shape of wings oval | <i>permodesta</i> Dyar. |
| Small, reddish brown, with a curved light line parallel to the distal margin | <i>byrne</i> Dyar. |
| Yellow, with a dull pinkish reddish margin | <i>aethes</i> Dogn. |

delphinii. **E. delphinii** Bsd. (= *strigata* Bsd., *quercicola* H.-S., *tardigrada* Clem., *monitor* Pack., *ferruginea* Pack., *bifida* Pack., *excisa* Wkr., *mira* Dyar) (164 i). The nomenclatural type is the eastern race. Hindwing dark brown, not much lighter than the forewing; the green on the forewing divided into a subbasal and subapical spot, each followed by red colour. — In **querceti** H.-Schäff. (164 i) the lower spot is split. — **interjecta** Dyar shows the two spots connected by a series of small green spots which in — **viridiclava** Wkr. (164 k) are united into a complete band, while in — **elliottii** Pears. they almost or entirely fill up the cellular space. The western race is — **paenulata** Clem. (164 k), with light yellow hindwings sometimes feebly strewn with brown outside; the green area of the forewing is somewhat smaller, so that a broad dark margin and a more or less distinct discal spot remain. Clermont, Massachusetts, New York, Maryland, Virginia, North Carolina. The form — **incisa** Harv. has a somewhat more extensive green, therefore narrow dark margins, and very light hindwings, Expanse of wings: ♂ 15—24, ♀ 24—30 mm. Wisconsin, Iowa, Nebraska, Florida, Missouri, Texas. The elliptical larva is flat, green or reddish, the horns short, with yellow subdorsal lines and dark undulating dorsal and lateral lines, but the ornamentation most variable. On trees and shrubs.

E. nanina Dyar (= *nana* Dyar nec H.-S.) (164 k) is smaller than *delphinii*, but of the same colour, the *nanina*. green well developed, composed of 2 round spots, the lower one split, the upper one circular, close together, the lower one followed by red colour. Expanse of wings: ♂ 15—19 mm; ♀ unknown. Florida.

E. aemilia Stoll (= *discolor* Sepp). Forewing dark brown, subbasal spot and subapical dots yellow, the *aemilia*. former followed by red colour; somewhat larger than *cippus*. The elliptical larva is flat, green, the lateral horns rather long, the subdorsal ones unequal, long at the ends, a group of 3 short ones close together subdorsally in the middle; a red dorsal stripe dispatching lateral branches in the middle and behind, with a lateral row of red spots. It lives on various kinds of forest-trees. Surinam.

E. cippus Cr. (164 k). Forewing dark red-brown, hindwing somewhat lighter. Forewing with 3 triangular *cippus*. green spots, the middle one generally as large as the subapical one, behind the subbasal red. Expanse of wings: ♂ 15—28, ♀ 20—32 mm. From Mexico to Paraguay except Brazil.

E. cipior Dyar (164 k) is larger than *cippus*, the green spots also larger. Hindwing light brownish. Ex- *cipior*. ppanse of wings: 29—33 mm. Peru (Santo Domingo).

E. norba Drc. (164 k). Forewing dark brown, hindwing lighter; the green spots as in *cippus*, but smaller, *norba*. the wings relatively longer and more rounded, the abdomen much longer, projecting beyond the hindwings. Expanse of wings: ♂ 22 — 30, ♀ 38—40 mm. Mexico, Central America, Panama, Ecuador, Colombia.

E. copac Schs. resembles *norba*, but its colouring is blackish, with more smoky brown hindwings. Ex- *copac*. ppanse of wings. ♂ 24 mm; ♀ unknown. Peru.

E. permodesta Dyar (164 k) has the shape of the wings and the long abdomen of *norba*, but without *permodesta*. green markings; forewing glossy dark brown, in a certain exposure to light transversely striated. Hindwing lighter brown, the inner margin dark. Expanse of wings. 24—28 mm; ♀ unknown. Guiana.

E. pallicolor Dyar (164 l). Light wood-brown, forewing with a white subapical streak and with a broken *pallicolor*. silvery subbasal marking, with darker brown colouring before them. Expanse of wings: ♂ 25 mm; ♀ unknown. French Guiana.

E. agchiatropha Dogn. (164 l). Cellular area and veins dark brown, the interspaces lighter with some- *agchiatro-* what erect scales; a subbasal silvery line extends inward on vein 1, yellowish-red colouring behind it, small sub- *pha*. apical silvery dots. Hindwing light brown with darker veins, fringe light. Expanse of wings. ♂ 27—30 mm; ♀ unknown. Colombia, Peru.

E. peroloides Dogn. Forewing silvery light brown, the scales between the veins somewhat erect, olive, *peroloides*. the colouring varying according to the exposure to light; a long oblique subbasal silvery stripe and 3 subapical silvery dots, not in one line, hindwing brownish, smoky outside. Expanse of wings. 28 mm; ♀ unknown. Peru (Yahuarmayo).

E. plugma Sepp (= *perplexa* Wkr., *zygia* Drc., *chiriquensis* Schs., *colle* Dyar) (164 l). Monotonously *plugma*. dark blackish brown, the markings often inconspicuous; an oblique subbasal straight silvery line and curved subapical row of 3 or 4 dots, sometimes also two silvery dots at the veins 2 and 3; the black discal dot not prominent. Hindwing dark brown. Expanse of wings: ♂ 12—20, ♀ 25—35 mm. SEPP figures a very large ♀ from Surinam (35 mm), the ♀ is invariably much larger than the ♂, whereas the ♀ of the northern race: — ~~hoboa~~ *hoboa*. *Schs.* is very small. The larva is elliptical, the lateral horns of medium length and smooth; the subdorsal horns with 3 rather long thorns at each end, the 5 middle ones short and smooth; green, the dorsum with a red, somewhat spotted band, a white line below the subdorsal horns. Surinam, Colombia, Panama, Costa Rica, Mexico.

E. determinata Drc. resembles *plugma*, the colour of the forewing varies from dark brown to light yellow; *determinata*. the markings are often extinct. Hindwing light brown, often yellowish, with a silky gloss, and darker veins. Expanse of wings: ♂ 14—20, ♀ 22—30 mm. In the form: — ~~costilinea~~ *Dyar* the subapical dots are connected. *costilinea*. Mexico, Central America, Colombia.

E. diversa Drc. (= *vericrux* Dyar) (164 l). Forewing dark brown with a long straight subapical silvery *diversa*. line and an undulate subbasal silvery line, a pinkish brown spot between them; discal dot dark brown, dark shades before the silvery markings. Very variable in the marking; in — *retroversa* *Dyar* the markings are less *retroversa*. distinct, the subbasal silver is irregular, and more or less distinct reddish colouring before it. Expanse of wings: ♂ 20—23, ♀ 22—32 mm. The elliptical larva is thick and small, the dorsal area dark blue, narrow, with a carmine dorsal line, irregularly widened on the expansions, one quadrangular carmine spot each on the rings 6, 7, 9 and 10; the subdorsal edge yellow, the sides green; the horns are thick and rather short, the subdorsal ones on the 5th and 11th rings being the longest. On different plants. Mexico, Guatemala.

- poasica*. **E. poasica** Dyar resembles *retroversa*, with quite indistinct markings, a large reddish spot behind the subbasal silver. Expanse of wings: ♂ 24—25 mm; ♀ unknown. Costa Rica.
- lamora*. **E. lamora** Dogn. (164 l) differs from *poasica* in much darker brown hindwings. Expanse of wings: ♂ 21—25 mm; ♀ unknown. Colombia.
- distragens*. **E. distragens** Dyar (164 l). Forewing wood-brown, without the red tinge of *diversa*, the marginal area, especially towards the anal angle, lighter yellowish; the subbasal silvery line obliquely outward, then inward along vein 1; hindwing light red-brown with a yellow reflection. Expanse of wings: ♂ 23—27 mm; ♀ unknown. Costa Rica, Panama.
- flava*. **E. flava** B. & McD. Quite light ochreous; subapical and subbasal silvery lines indistinctly connected by a dark curved shadow. ♂ still unknown, expanse of wings: ♀ 22 mm. Arizona.
- dolliana*. **E. dolliana** Dyar (164 l). Monotonously red-brown; a subapical bent silvery streak, the subbasal silvery line undulate, thick, blackish before and behind it. Hindwing dark red-brown. ♂ unknown. Expanse of wings: ♀ 27 mm. Costa Rica, Arizona.
- spadicis*. **E. spadicis** Grossbeck. Forewing monotonously red-brown, the hindwing lighter. The subbasal silvery streak oblique, somewhat undulate, no other marking. Expanse of wings: ♂ 20 mm. ♀ unknown. Arizona.
- bidiscalis*. **E. bidiscalis** Dyar (= *doriens* Schs.) (165 a). Dark purple blackish, watered somewhat darker; the subbasal silver extinct, but small subapical silvery dots, and one on vein 3, the disc hyaline on both wings. Expanse of wings: ♂ 20—23 mm; ♀ unknown. Guatemala, Panama, Colombia.
- immundara*. **E. immundara** Dyar (165 a). Forewing olive brown, yellowish, with 3—5 more or less connected subapical silvery dots, the subbasal silvery marking angular, undulate; the ground mixed with blackish, especially basally and on the veins, a streak behind the cell; marginal area more or less spotted, especially in the middle; discal dot absent. Hindwing brown, with darker veins, fringe yellow. Expanse of wings: ♂ 22—24, ♀ 27—28 mm. Mexico (Tabasco), Guatemala.
- cassida*. **E. cassida** Dyar (165 a). Forewing with a light yellowish ground-colour, the scales somewhat erect and thin, speckled blackish especially basad, defining a light pink spot which is situate between the subapical silvery dots and the subbasal strongly undulated line; discal dot absent. Hindwing somewhat lighter than in *immundara*. Expanse of wings: ♂ 23—24 mm; ♀ unknown. Brazil (Amazons).
- rufa*. **E. rufa** Btlr. "Red-brown, opalescent in the disc between the veins, dark reddish brown in the disc and below it, the inner margin, distal margin and veins light, with a silky gloss; subapical silvery dots, the subbasal silvery line strongly angled; a dark discal dot. Expanse of wings: ♂ 25 mm; ♀ unknown." Brazil (São Paulo). The species had been considered a synonym to *perplexa* Wkr. (by me in 1905 and once more in 1926); but BUTLER's description refers more to a species allied to the following *baranda*. In 1911, SCHAUUS examined the type of *rufa* and ascertained that it is different from *perplexa*, yet this statement had been forgotten until some time ago.
- baranda*. **E. baranda** Schs. (165 a). Forewing dark reddish brown with a large round discal dot, the ground only slightly irrorated darker; a flesh-coloured spot between the subapical silvery dots and the subbasal line is U-shaped in the middle. Hindwing lighter brown with darker veins and brown fringe. Expanse of wings: ♂ 24 to 28 mm; ♀ unknown. Colombia.
- jelyce*. **E. jelyce** Dyar is smaller than *baranda*, with more pointed wings, somewhat more scantily scaled, the apical veins more prominent. Expanse of wings: ♂ 20—23 mm; ♀ unknown. Costa Rica, Panama.
- buscki*. **E. buscki** Dyar (165 a) is somewhat smaller than *jelyce*, the wing opaque, dark brown, with a but feebly reddish area between the subapical dots and the U-shaped subbasal silvery line; discal dot present, but indistinctly marked. Hindwing dark brown. Expanse of wings: ♂ 18—21 mm; ♀ unknown. Panama (Canal Zone).
- trichathdota*. **E. trichathdota** Dyar. Forewing dark brown, dusted reddish subapically and subbasally, the distal veins and vein 1 whitish; the subapical silver extinct, the subbasal marking is a widely open slender crescent; hindwing black. Expanse of wings: ♂ 18 mm; ♀ unknown. Costa Rica, Panama.
- cuspostriga*. **E. cuspostriga** Dyar (165 a) differs from the preceding species in the short and thick subbasal silvery crescent. Expanse of wings: ♂ 14—17 mm; ♀ unknown. Guiana.
- byrne*. **E. byrne** Dyar (165 a) shows the wings shaped like *determinata*, the wings reddish brown, the hindwings redder than the forewings; a very feeble bent light distal line extends from the costal margin before the apex to the centre of the inner margin, the colour before it being somewhat darker; no other markings. Expanse of wings: ♂ 12—16 mm; ♀ unknown. Guatemala, Costa Rica.

E. aethes *Dogn.* (165 b). Light yellow, with a broad light pink area along the distal and inner margins. *aethes*. Hindwing light yellowish. Expanse of wings: ♂ 22—24 mm; ♀ unknown. Colombia.

12. Genus: **Talima** *Wkr.*

Very closely allied to the preceding genus, distinguished by more slender palpi with a more distinct terminal joint. The colouring of the forewing is more distinctly red-brown and ochreous in various tints.

T. straminea *Schs.* (165 b). Wings of a broad, triangular shape; forewing reddish yellow, shaded brown *straminea*, along the inner and distal margins, the veins and a slightly undulated distal line brown; an oblong oval reddish subbasal area. Hindwing brown, lighter along the costal margin, the veins distinct in the ♂, vanishing in the ground in the ♀. Expanse of wings: ♂ 20—23; ♀ 25—27 mm. Mexico and Costa Rica.

T. sissypha *Dyar* (165 b) resembles *straminea*, but the whole forewing is darkened purple brown. Inner *sissypha*, and distal margins still darker, the reddish subbasal area brightly contrasting. Hindwing much darker brown than in *straminea*. Expanse of wings: ♂ 21 mm; ♀ unknown. Guatemala.

T. ingenour *Dyar*. Wings long and narrow, both the forewings and hindwings, the markings as in *sissypha*, a yellowish apical spot just as distinct as a subbasal one. Expanse of wings: ♂ 20—25 mm; ♀ unknown. Colombia, Guiana, Brazil (Amazons).

T. aurora *Dyar* (165 b) differs from *ingenour* in the lighter ground-colour of the forewing, powdered *aurora*, with yellow, the veins distinctly marked. Expanse of wings: ♂ 22—25 mm; ♀ unknown. Costa Rica, Panama.

T. flexilinea *Dyar* (165 b). Forewing dark brown, only with a fine exterior line bending towards the *flexilinea*, inner margin; behind it at the apex there is a large dark purple grey shadowy spot; hindwing darker brown; ♂ unknown. Expanse of wings: ♀ 24—26 mm. French Guiana.

T. varians *Dyar* (165 b). Forewing light purple brown, shaded darker basally, the veins darker outside, *variens*, traversing the fine undulatingly bent exterior line behind which there is a broad dark purple brown apical spot. Hindwing light yellowish straw-coloured with a purple grey area through the centre. ♂ unknown; ♀ 23 mm. Venezuela.

T. columbiana *Dogn.* (165 b). Forewing lustrous light reddish brown, the veins finely darker; the exterior *columbiana*, line rather broad and straight, from the costal margin before the apex to the middle of the inner margin. Hindwing light brown; ♂ unknown; expanse of wings; ♀ 30 mm. Colombia.

T. phara *Drc.* Greyish reddish brown; a discal spot, the veins partly, and a fine exterior line dark brown, *phara*, the marginal area behind it indistinctly more shaded purple; hindwing dark red-brown, dusted blacker in the ♀ than in the ♂. Expanse of wings: ♂ 15, ♀ 21—25 mm. Described according to specimens from French Guiana; DRUCE's type from Colombia.

T. rubicolor *Dyar* (= *parva* *Dyar*, *aphasia* *Dyar*) (165 b) is smaller and more reddish than *phara*, the *rubicolor*, marginal area in the ♀ less shaded darker or not at all; the forewing of the ♂ is more or less, often very intensely, tinged with dark purple brown, the veins often striped darker. Hindwing of the ♀ dark brown, of the ♂ lighter with striped veins. Expanse of wings: ♂ 15—19, ♀ 16—22 mm. Nicaragua, Costa Rica, Panama, Venezuela.

T. assimilis *Dyar* (165 c) has rather dark red-brown forewings with a traceable discal dot and a fine, *assimilis*, slightly undulated dark exterior line; marginal area a bit more purple. Hindwing blackish brown. ♂ unknown; ♀ 15—20 mm. East Mexico.

T. emilia *Dyar* resembles *rubicolor*, somewhat more intensely suffused with brown, the exterior line in- *emilia*, distinct. Hindwing yellowish straw-coloured, with a dark spot at the anal angle. Expanse of wings: ♂ 15—20 mm; ♀ unknown. Guatemala, Costa Rica, Panama, Colombia, Venezuela, French Guiana, Brazil (Amazons).

T. meritone *Dyar* (165 c) is larger than *emilia*, the forewing intensely suffused with dark, the veins not *meritone*, striped, with a rounded clouded discal area. Expanse of wings: ♂ 22—23 mm; ♀ unknown. Colombia.

T. insulla *Dyar* resembles the following *sulla*, but the dark exterior line is absent and replaced by a fine *insulla*, light yellow line which is indistinct in the ♂, distinct in the ♀. Expanse of wings: ♂ 20, ♀ 26 mm. Brazil (Amazons).

T. sulla *Schs.* (165 c). Forewing reddish brown basally, with darker veins; the exterior transverse line *sulla*, fine, dotted on the veins, the area behind it violettish grey; hindwing light yellow, with a small dark spot at the anal angle. Expanse of wings: ♂ 20—22 mm; ♀ unknown. Brazil.

T. ieco *Dyar* resembles *sulla*, but it is smaller, the forewing more intensely suffused with dark, red at *ieco*, the inner margin. Expanse of wings: ♂ 16—19 mm; ♀ unknown. It may be only a form of *sulla*. Brazil. Paraguay.

latescens. **T. latescens** Btlr. Forewing light yellowish brown, with traces of a discal dot, no dark dusting, with dark veins; exterior line fine and straight, the marginal area more violettish grey. Hindwing orange straw-coloured, more or less tinged with dark at the inner margin. Expanse of wings: ♂ 17—21 mm; ♀ unknown. Colombia, Peru, Brazil (Amazons).

massanaria. **T. massanaria** Dogn. resembles *latescens*, but it is somewhat smaller. ♀ more red-brown, the veins not darker. Hindwing dark red-brown. Expanse of wings: ♂ 14, ♀ 17 mm. Brazil (Santarem).

postica. **T. postica** Wkr. Forewing pointed triangular, scantily scaled, with prominent veins; exterior line indistinct, slightly bent, violettish grey, the ground-colour before it more or less red, violettish grey behind it. Hindwing orange with a large violettish grey spot at the produced anal angle. Expanse of wings: ♂ 16—22 mm; ♀ unknown. Venezuela, Guiana, Paraguay, Brazil (Amazons).

filifera. **T. filifera** Dyar (165 c) is larger than *postica*, the forewing more intensely dusted with violettish grey. It may be only a form of *postica*. Expanse of wings: ♂ 20—24 mm; ♀ unknown. Guiana, Bolivia, Brazil.

13. Genus: **Adoneta** Clem.

Spur present on the posterior tibia. Not all the veins present on the forewing. Small insects allied to the *Euclea*, recognizable by the slightly produced apex of the forewing. *Cyclopteryx* Pack. is a synonym to *Adoneta*.

spinuloides. **A. spinuloides** H.-S. (= *voluta* Clem., *ferrigera* Wkr., *ruptilinea* Wkr., *leucosigma* Pack., *nebulosus* Wetherby) (165 c). Forewing cinnamon brown with bent subbasal and subapical silvery lines inwardly bordered with grey, more distinctly in the ♂ than in the ♀, connected by a bent row of black dots; a small oblong black spot at the cell-end, prolonged by a shadow. Hindwing brown, fringe lighter. Expanse of wings: ♂ 15—18, ♀ 15—23 mm. The elliptical larva exhibits 2 rows of special tubercles, the subdorsal ones on the anterior and posterior segments are longer and of red colour; ground-colour green, dorsal area yellow, broadly filled up by an undulated violettish red band, strongly strangulated behind the middle. It lives on different trees in the forests and on shrubs. New Hampshire, New York, Maryland, North Carolina, Florida, Texas.

bicaudata. **A. bicaudata** Dyar has light yellow forewings, the margins tinged with brown, of a purer yellow in the ♂ than in the ♀; silvery lines and black dots as in *spinuloides*, but the blackish shadow at the discal dot is absent. Forewing light yellowish brown. Expanse of wings: ♂ 14—17, ♀ 17—18 mm. Larva oblong elliptical with parallel lateral margins, the last pair of horns very much prolonged; green, dorsal area and horns red; an undulated violettish red dorsal band forms 3 expansions each on the anterior and hindmost segments and is very narrow in the middle. On different trees in forests and on shrubs. New Jersey, Maryland, North Carolina.

pygmaea. **A. pygmaea** G. & R. (165 c). Forewing bright light brown without grey shading; silvery lines as in the two preceding species, but less distinct, the black dots traceable with a more or less distinct dark shadow through the marking; discal dot absent. Hindwing light brown. Expanse of wings: ♂ 12—14, ♀ 16 mm. Central Texas.

gemina. **A. gemina** Dyar resembles *pygmaea*, but the brown shadow in the markings is more interrupted, the ground-colour is a duller light brown, and the hindwing is blackish brown. Expanse of wings: ♂ 12—14, ♀ 15 mm. South Texas.

14. Genus: **Monoleuca** G. & R.

Separated from the preceding genus merely by the somewhat different shape of the wings, a more rectangular, not sickle-shaped apex, the distal margin uniformly curved.

Type: *M. semifascia* Wkr.

occidentalis. **M. occidentalis** B. & McD. (= *fieldi* B. & Benj.) shows lighter or darker brown forewings with darker shades indicating the position of the extinct subbasal and subapical lines, sometimes slightly scaled white. Forewing light brown, varying in intensity. Expanse of wings: ♂ 17—21 mm; ♀ unknown. South California (S. Diego).

disconcolorata. **M. disconcolorata** B. & Benj. differs from *occidentalis* in the glossy silky yellowish white or almost white hindwings. Expanse of wings: ♂ 21 mm; ♀ unknown. South California (S. Bernardino Mts.).

semifascia. **M. semifascia** Wkr. Forewing dark red-brown with a straight silvery line in the basal third from the inner margin into the cell; this line is thick and forms upwards two distal dents. Hindwing lighter brown. Expanse of wings: ♂ 14—20, ♀ 22—25 mm. The stout elliptical larva shows 2 rows of spined tubercles, the anterior pair of each row and the posterior pair of the subdorsal row prolonged into horns. Colour dull violettish brown.

with red stripes along the rows of thorns and undulate dark brown lines between them. It lives on many trees in forests and on shrubs. Virginia, North Carolina, Florida, Texas.

M. sulfurea Grt. (= *erectifascia* Dyar) (165 d) differs from *semifascia* in the straighter finer line. the *sulfurca*. feebler dents not being silvery but light yellow. Expanse of wings: ♂ 15—18 mm; ♀ unknown. Florida.

M. subdentosa Dyar (165 d) is very similar to *semifascia*, but the silver line is narrow, twice very *subdentosa*. strongly dentate, with reddish colouring before it. Expanse of wings: ♀ 24 mm; ♂ unknown, Florida.

M. angustilinea Dyar (165 d). Forewing monotonously red-brown, the silver line straight, of a sulphur *angustilinea*. tint, fine and of a somewhat oblique course, entering the cell before the origin of vein 2, and with faint reddish colouring before it. Expanse of wings: ♀ 23 mm; ♂ unknown. Florida.

M. obliqua H. Edw. Monotonously brown, the silvery line very oblique, almost from the base to the *obliqua*. apex. Hindwing much lighter than the forewing. Expanse of wings: ♂ 16 mm; ♀ unknown. Florida.

15. Genus: **Epiclea** Dyar.

Very similarly built as *Zaparasa*, but vein 10 of forewing stalked with 7 and 8; 9 absent. Hind tibiae without spurs. Only 1 species:

E. elaea Drc. (165 d). Forewing light reddish brown, monotonous; a rather narrow straight white line *elaea*. extends parallel with the distal margin from behind the middle of the inner margin to the cell-end. Hindwing light brownish wood-coloured, dusted somewhat blackish. Expanse of wings: ♂ 20 mm; ♀ unknown. Mexico; Panama. This description is based upon a specimen denoted as the "type" in the Coll. DRUCE. The specimen figured in the "Biologia" (pl. XXIII, fig. 14), now in the Berlin Museum, is *Euprosterna eleaeasa* Dyar.

16. Genus: **Miresa** Wkr.

Spurs of hind tibiae present; forewing with all the 12 veins. Palpi short, not reaching the frontal tuft. Basal thirds of ♂ antennae pectinate, then shortly serrated decreasing apically. The genus is also represented by numerous species in the Indo-Australian Region and occurs also in the Palaearctic Region.

Type: *M. albipuncta* H.-S.

M. clarissa Stoll (= *argentata* Wkr.) (165 d). Dark red-brown, of a variable tint; an undulate silvery *clarissa*. postmedian line and small silvery spots at the margin; thorax more or less mixed with yellow. Expanse of wings: ♂ 25—30, ♀ 35—40 mm. Mexico, Central America, Colombia, Venezuela, Guiana, Brazil.

M. argentea Drc. (165 d). Dark red-brown, mixed with yellow, especially on the thorax; 2 fine brown *argentea*. lines, convergent towards the costal margin, the interior one strong and irregularly angled, the exterior one undulate and curved. The ♀ with more indistinct lines, the exterior one strewn with silver. Hindwing blackish, fringe yellow. Expanse of wings: ♂ 26—28, ♀ 37 mm. From Mexico.

M. fuscoflava Dogn. (165 d). Disc of forewing light brownish, blackened towards the apex, the apex *fuscoflava*. itself and the inner-marginal part yellow, some black scales subbasally; subapical yellow dots and black ones behind them. Hindwing light brownish. Body rather light. tegulae yellowish. Expanse of wings: ♂ 31—34 mm; ♀ unknown. Ecuador, Colombia.

M. venosa Dyar (165 e) is a small species. Forewing violettish grey, lighter towards the margin, with *venosa*. 2 parallel dentate oblique postmedian lines. Hindwing light yellowish straw-coloured. Expanse of wings: ♂ 20—22 mm; ♀ unknown. San Salvador.

17. Genus: **Sisyrosea** Grt.

Antennae of ♂ bipectinate almost to the tips; palpi short, not reaching the vertex. Veins 2 and 3 of forewing arise separately; hind tibiae only with terminal spurs. Synonyms of the genus: *Isa* Pack., *Sosiosa* Ry., *Sicyrosea* Pack. Type: *S. inornata* G. & R.

S. diana Drc. Thorax and forewing dark rust-brown, passing over into black towards the margin. *diana*. Hindwing black, mostly scantily scaled in the disc. Wings rather narrow, apex produced. Expanse of wings: ♂ 19—23 mm. ♀ unknown.

S. textula H.-Schäff. (= *inornata* G. & R.). Forewing lustrous light brown, scaled in a somewhat wrinkl- *textula*. ed way; ♂ with a dark brown basal shadow and another submarginal one, reddish towards the inner margin. ♀ the same, but mostly lighter and with hardly any marking. Hindwing red-brown. Expanse of wings: ♂ 17 to 19, ♀ 18—23 mm. Larva very flat, the dorsal area strangulated, the subdorsal horns small, the lateral ones thin, fringe-like; green, a small red spot in the centre of the dorsal area. New York, Maryland, Virginia, North Carolina.

- schaefferana*. **S. schaefferana** Dyar (165 e). Light brown, monotonous, the wings wrinkled, from a light brownish wood-colour to reddish brown. Expanse of wings: ♂ 22—28, ♀ 26—30 mm. South Arizona.
- obscura*. **S. obscura** Dyar (165 e). Forewing dark purple brown, scantily strewn with black. Hindwing somewhat more reddish brown. Expanse of wings: ♂ 17—20 mm; ♀ unknown. French Guiana.
- brusha*. **S. brusha** Dyar (165 e). Forewing purple brown, spotted reddish in the inner-marginal half, little or not at all strewn dark; hindwing distinctly blackish. Expanse of wings: ♂ 20 mm; ♀ unknown. Mexico; French Guiana.

18. Genus: **Euprosterna** Dyar.

Antennae of ♂ slender, with short double pectinations; palpi with a short obtuse terminal joint, almost reaching the vertex. Neuration as in *Sisyrosea*. Hind tibiae with both pairs of spurs.

Type: *E. aroënsis* Schs.

- urba*. **E. urba** Drc. Forewing dark brown, with a green subbasal strigiform spot and a green subapical dot as well as traces of a dark distal band. Hindwing lighter brown. Expanse of wings: ♂ 18 mm; ♀ unknown. Costa Rica.
- pernambuconis*. **E. pernambuconis** Dyar (165 e). Brown, with 2 white lines convergent towards the costal margin, the exterior line approaching the margin towards the inner margin. Hindwing light blackish. Expanse of wings: ♂ 13—14 mm; ♀ unknown. Brazil (Pernambuco).
- cochlidionis*. **E. cochlidionis** Dyar (165 e). Forewing light ochreous, with 2 fine dark lines convergent towards the costal margin, the interior one twice almost rectangularly broken along the submedian fold. Expanse of wings: ♂ 15—17 mm. ♀ unknown. Mexico.
- lacipecta*. **E. lacipecta** Drc. Very dark brown, the forewings marked as in *cochlidionis*, but the lines are light, the interior one only curved, not twice angled, the exterior one touching the distal margin in the middle. Hindwing blackish. Expanse of wings: ♂ 17—19 mm; ♀ unknown. Mexico.
- elacasa*. **E. elacasa** Dyar (= *avellana* Dgn.) (165 f). Rather dark brown, with but one dark line bordered with light outside. Hindwing dark brown. Expanse of wings: ♂ 15—16 mm; ♀ unknown. Central America, Panama, Colombia, Guiana, Trinidad, Brazil.
- hosia*. **E. hosia** Dyar (165 f). Forewing dark brown, with a bronze reflection towards the anal angle; irregular black markings in the disc indicate traces of lines. Hindwing brownish black. Expanse of wings: ♂ 15—18 mm; ♀ unknown. Costa Rica (Carillo).
- aroënsis*. **E. aroënsis** Schs. (165 f). Forewing brown with a silky gloss, dark at the base, somewhat oblique, sharply defined; with a discal dot; indistinct transverse wrinkles in the distal part. Hindwing light brownish. Expanse of wings: ♂ 14—18, ♀ 19 mm. Panama, Venezuela, Trinidad.
- cora*. **E. cora** Schs. (165 f) is smaller than *cochlidionis*, browner, the markings similar, but interrupted and indistinct; the exterior line extends towards the distal margin more like that in *lacipecta* and cuts off a grey apical part; interior line dark, angled, indistinctly bordered with light; hindwing from yellowish straw-coloured to dark grey. Expanse of wings: ♂ 12—17 mm; ♀ unknown. Mexico (Sinaloa).
- notula*. **E. notula** Dgn. (165 f). Rather light ochreous, scantily strewn with black scales, with an indistinct broad brown submarginal band enclosing 2 small black spots towards the apex. Hindwing light blackish. Expanse of wings: ♂ 17 mm; ♀ unknown. Peru (Yahuarmayo).
- sapucaya*. **E. sapucaya** Dyar (165 f). Dark pinkish brown, lighter and somewhat more yellowish along the inner margin, pale lilac towards the distal margin; a dark-shaded band extends in a curve from near the base of the inner margin gradually vanishing to the centre of the wing. Hindwing pinkish brown with a dark spot at the anal angle. Expanse of wings: ♂ 15 mm; ♀ unknown. Paraguay.
- vagabunda*. **E. vagabunda** Dyar (165 f). Pinkish brown, narrowly yellow at the margin; an indistinct dark spot in the centre of the wing represents the angle of the extinct interior line. Expanse of wings: ♀ 16—20 mm; ♂ unknown. Mexico.

19. Genus: **Platyprosterna** Dyar.

Separated from the preceding genus by stronger antennae with broader double pectinations. Only 3 species:

Type: *P. elaeetta* Dyar.

- elaeetta*. **P. elaeetta** Dyar (165 f). Forewing brown in the basal half, lilac in the distal half, the two halves separated by an oblique median line bordered with dark inside, with light outside; no submarginal line. Hindwing light brown. Expanse of wings: ♂ 20—23 mm; ♀ unknown. Brazil.
- antiqua*. **P. antiqua** Dyar (165 e). Forewing brownish ochreous in the basal half, light yellowish brown in the distal half, divided as in *elaeetta* outside with a fine dark subterminal line extending analwards to the margin. Hindwing whitish ochreous. Expanse of wings: ♂ 18 mm; ♀ unknown. Brazil.

P. ceres *Drc.* (165 e). Greyish brown with a broad blackish submarginal shadow which is incurved *ceres*. outside in the middle; a whitish inner-marginal area extends almost to the median vein, and a light oblique strigiform spot extends from the base of the inner margin upwards outside. Hindwing dark greyish brown, fringe light. Expanse of wings: ♂ 20—24, ♀ 24—26 mm. Mexico, Guatemala; S. Salvador.

20. Genus: **Natada** *Wkr.*

Antennae of ♂ bipectinate almost to the tips, the obliquely upturned truncate palpi project beyond the frons. Veins 2 and 3 of forewing arise separately, vein 7 arises from vein 6 remote from the cell. The genus contains a great number of mostly larger species of a robust build. *Bombycocera* *Fldr.* and *Rhinaxima* *Bar* are synonyms. As the species are often difficult to distinguish, we supply again an analytical table.

Type: *N. rufescens* *Wkr.*

Synopsis of Species.

1. Forewing with an exterior straight line and an interior oblique line, both equably distinct and similar 2
Forewing not marked that way 11
2. Lines dark on a light ground 3
Lines light on a dark ground 8
3. ♂ antennae with long pectinations *perpectinata* *Dyar.*
♂ antennae with moderately long or short pectinations 4
4. The lines of the forewing meet at the costal margin ♀-*subpectinata* *Dyar.*
Lines separated at the costal margin 5
5. A large species, forewing yellowish straw-coloured *cochuba* *Schs.*
Smaller, forewing brown 6
6. Antennae dark brown *nucea* *Dogn.*
Antennae yellow 7
7. A larger species, wings mostly darker *daona* *Drc.*
Smaller, wings mostly dusted lighter *nasoni* *Grt.*
8. Larger, hindwing greyish brown 9
Smaller, hindwing blackish 10
9. A very large species, the light lines shaded *mycalia* *Stoll.*
Somewhat smaller, the light lines fine, bordered with dark *fusca* *Drc.*
10. The light lines intensely bordered with brown, ♂ antennae apically serrate ♂-*subpectinata* *Dyar.*
Light lines without dark borders, ♂ antennae pectinated to the tips *fuscodivisa* *Dogn.*
11. Forewing with a straight dark distal line, the interior one absent 12
Forewing without any distinct coherent lines 17
12. Forewing dark brown as far as the exterior line, the margin contrastingly lighter *simois* *Stoll.*
Forewing without a contrastingly lighter marginal area 13
13. Very small (15—18 mm), exterior line near the margin *caria* *Drc.*
Larger (20—38 mm) 14
14. Exterior line bordered with light outside 15
Exterior line fine, without a light border 16
15. Smaller (20—30 mm) *pucara* *Dogn.*
Larger (37 mm) *increscens* *Dyar.*
16. Smaller, hindwing lighter than forewing *miradora* *Dyar.*
Larger, hindwing darker than forewing *arpi* *Dyar.*
17. Very large and robust (45—48 mm), light, abdomen reddish above *sufficiens* *Dyar.*
Smaller (32—37 mm), thorax and forewing of a fiery red tint *incandescens* *Dyar.*
Medium-sized, without red colour, wings wrinkled, glossy 18
18. Small (17 mm), light straw-coloured, a small discal dot *molicula* *Dogn.*
Larger, differently tinged, brown with a silky gloss 19
19. Forewing with more or less distinct, faded exterior lines and oblique interior lines, the latter forming a demi-band at the inner margin 20
Without this marking 24
20. Forewing with a silky gloss, only little wrinkled 21
Forewing strongly wrinkled, with a silky gloss 22
21. Exterior line bent, touching the distal margin; hindwing light brown *nindla* *Dyar.*
Exterior line fine, indistinct beneath, hindwing blackish *barranca* *Schs.*

22. Exterior line of forewing only traceable 23
 This line absent, a shaded demi-band at the inner margin *quadrata* Wkr.
 23. Small, with narrow wings, of a reddish tint *deba* Dyar.
 With broader wings, dark brown without a reddish tint *styse* Dyar.
 24. Distal margin of forewing angled, upper surface finely wrinkled 26
 25. Larger, darker, wrinkles of forewing more separated and not numerous *ulaula* Dyar.
 Smaller, lighter, wrinkles of forewing nearer together and more numerous *michorta* Dyar.
 26. Wings without spots *lucens* Wkr.
 Wings with but one discal dot *sardites* Drc.
 Wings with a discal dot and a dot on the discal fold *debella* Dyar.
 Wings only with a spot on the discal fold *dognini* Dyar.

perpectinata.

N. perpectinata Dyar (165 g). Bright reddish brown, the basal area slightly darkened; the lines dark, the exterior one rather *indistinct*, the interior one bordered with light outside. Hindwing rather light brown with a grey tint. Expanse of wings: ♂ 24 mm; ♀ unknown. Brazil.

subpectinata.

N. subpectinata Dyar (= *urichia* Schs.). In the ♂ the lines exhibit strong white borders, so that they appear light on a dark ground, in the ♀ the ground-colour is lighter brown and the lines appear therefore darker. Expanse of wings: ♂ 17—20, ♀ 20—23 mm. The larva was found by F. W. URICH on cocoa-nut palms, but he did not supply a description. Guiana; Trinidad.

nucea.

N. nucea Dgn. (165 g). Dark brown, the lines dark, without white borders, separated at the costal margin. Antennae dark brown. Expanse of wings: ♂ 20 mm; ♀ unknown. French Guiana.

daona.

N. daona Drc. (165 g). Lighter or darker brown, the lines distinct, bordered with light outside, separated at the costal margin. Hindwing generally blackish. Expanse of wings: ♂ 21—25, ♀ 30—33 mm. Mexico, Guatemala. It is very similar to *nasoni*.

nasoni.

N. nasoni Grt. (= *rude* H. Edw.). Forewing whitish brown, strewn darker with distinct dark lines which are rather broad, the interior one slightly bent. Hindwing light blackish. Expanse of wings: ♂ 20—22, ♀ 23—24 mm. Larva rather stout, quadrangular, green, marked with undulating yellow lines and a straight yellow subdorsal line; horns very short, mostly red, the two posterior ones projecting as short distantly separated tails. It lives on low oak-bushes. New York, Virginia, North Carolina.

fuscodivisa.

N. fuscodivisa Dgn. (165 g) has dark bronze brown forewings with narrow light lines, inwardly bordered with more distinct bronze shading; they meet at the costal margin. Hindwing black. Expanse of wings: ♂ 25 mm; ♀ unknown. French Guiana; Surinam.

fusca.

N. fusca Drc. (= *salta* Drc.). From very dark to light reddish brown, the light lines meeting almost or entirely at the costal margin, the exterior one shaded with reddish inside, the interior one with a blackish border which is often as distinct as the line itself. Hindwing from bronze brown to blackish. Expanse of wings: ♂ 25—35, ♀ 40—42 mm. Mexico, Central America, Panama, Colombia, Venezuela.

mycalia.

N. mycalia Stoll (165 g). Forewing dark brown, more grey at the margin, the broad lines light loam-coloured, somewhat faded; the veins bordered with light outside. Hindwing lighter brown, the veins likewise somewhat light-striped outside. Expanse of wings: ♀ 46 mm, ♂ unknown. A. HEMPEL sent cocoons of this species, but wrote nothing about the larva. The larva figured by STOLL does not belong to this species. Guiana, Brazil.

simois.

N. simois Stoll (= *abscissa* Wkr., *senilis* Fldr.) (165 g) has dark brown forewings with a violet tint as far as the dark exterior line, yellowish straw-coloured behind it, more or less intensely shaded with lilac. Hindwing blackish brown. Expanse of wings: ♂ 28—35 mm; ♀ unknown. Guiana, Bolivia, Brazil (Amazons).

caria.

N. caria Drc. is a small species with mouse-coloured wings, a dark discal dot and a straight brown shaded line close at the margin. Hindwing coloured the same. Expanse of wings: ♂ 15—16, ♀ 17—20 mm. Panama, Guatemala.

pucara.

N. pucara Dgn. (= *quadrata* Berg nec Wkr., *bergii* Dyar) (165 h). Forewing from dark violettish brown to light greyish brown, thorax and abdomen above more or less tinged with dark fiery red; exterior line near the margin, bordered somewhat light outside, and an oblique line from the base of the inner margin to the cell-end; here there is a small dark discal dot. Hindwing variable, lighter or darker. Expanse of wings: ♂ 25 to 30, ♀ 37 mm. Colombia, Guiana, Bolivia, Peru, Brazil, Argentina.

increscens.

N. increscens Dyar (165 h) is similar to *pucara*, but much larger, a large dark form. Expanse of wings: ♂ 38—40 mm; ♀ unknown. Guinea.

miradora.

N. miradora Dyar (165 h) resembles a small dark *pucara*, but the exterior line is interrupted beneath by a large round bronze shadow on the anal angle; basal area darkened. Hindwing brown. Expanse of wings: ♂ 25 mm, ♀ unknown. Mexico.

N. arpi Dyar. Larger than *miradora*, with the same markings, the forewing light greyish brown, the *arpi*. hindwing dark mouse-coloured greyish brown. Expanse of wings: ♂ 37 mm, ♀ unknown. Brazil.

N. sufficiens Dyar (165 h). Large and robust; forewing light straw-coloured, slightly shaded with violetish grey, the lines scarcely traceable; a dark discal dot at the cell-end. Hindwing light yellowish with a feeble pinkish brown tint. Expanse of wings: ♂ 43–48 mm; ♀ unknown. French Guiana.

N. incandescens Dyar (165 h) has a fiery red thorax and dorsum of the abdomen; wings reddish brown, *incandescens*. forewing with a slight bronze gloss, tinged with violet in the disc, crossed by three vertical broad badly defined dark bands. Expanse of wings: ♂ 28–37 mm; ♀ unknown. Colombia, French Guiana, Brazil (Amazons).

N. molicula Dgn. (165 h). Small, light straw-coloured, forewing winkled, a discal dot may be present *molicula*. or absent. Expanse of wings: 17–20 mm; ♀ unknown. Argentina.

N. nindla Dyar (165 i). Thorax and abdomen with yellow tufts; forewing purple brown, lighter V-shaped *nindla*. between the line; the exterior line extends, cutting off the apex, to the distal margin above the anal angle, the interior oblique line is shaded and only indistinctly visible as far as the costal margin. Forewing yellowish brown. Expanse of wings: ♂ 25–28 mm; ♀ unknown. Costa Rica; Panama.

N. barranca Schs. is more rusty brown, the lines feebly indicated by streaks or small spots, the basal *barranca*. area darkened. Hindwing blackish brown. Expanse of wings: ♂ 23–24 mm; ♀ unknown. Guatemala.

N. deba Dyar (165 i) has dark brown wings with a slight rust-brown tint, with a blackish submarginal *deba*. line which, however, is only traceable in its upper half, and an oblique line in the middle, of which only the lower half is present, both shaded, almost parallel; a dark discal dot. Hindwing reddish brown, more or less dusted blackish. Expanse of wings: ♂ 20–24 mm; ♀ unknown. French Guiana.

N. styx Dyar (165 i). Like *deba*, but darker brown, the lines extinct, separating below. Hindwing *styx*. blackish. Expanse of wings: ♂ 28 mm; ♀ unknown. Peru.

N. quadrata Wkr. Brownish straw-coloured, wrinkled, with a silky gloss, a dark faded demi-band at *quadrata*. the inner margin. Expanse of wings: ♂ 25 mm; ♀ unknown. Venezuela.

N. michorta Dyar (165 i) has dark violet forewings with a silky bronze lustre, a somewhat convex distal *michorta*. margin, the hindwing somewhat angular in the middle, with traces of several dark transverse bands. Hindwing light reddish brown. Expanse of wings: ♂ 25–30 mm; ♀ unknown. Costa Rica, Guatemala.

N. ulaula Dyar (165 i) is larger than *michorta* and darker, the indicated transverse lines more separated *ulaula*. and less numerous. Expanse of wings: ♂ 30 mm; ♀ unknown. Colombia.

N. lucens Wkr. The somewhat wrinkled forewing pinkish brown with a silken gloss, with a rounded *lucens*. distal margin. Hindwing pinkish brown, sometimes shaded with blackish, the abdomen above more or less tinged reddish. Forewing either with no markings (*lucens*), or only with a discal dot: — **sardites** Drc. (= *nigri-sardites*. puncta B. & McD.), or with a discal dot and another dot on the discal fold: — **debella** Dyar, or only with a *debella*. dot on the discal fold: **dognini** Dyar (165 i). Expanse of wings: ♂ 20–30, ♀ 30–35 mm. Arizona, Mexico, *dognini*. Central America, Colombia, Venezuela, Guiana, Brazil.

21. Genus: **Cnidocampa** Dyar.

Distinguished by plain, somewhat flattened antennae and palpi which are thrice as long as the head, erect, with a pointed terminal joint. Only 1 species.

C. flavescens Wkr. Thorax and base of forewing yellow, the distal part pinkish brown, enclosing two *flavescens*. oblique dark lines nearing each other before the apex at the costal margin; a brownish discal dot at the cell-end. Hindwing light yellowish brown. Expanse of wings: ♂ 27, ♀ 30 mm. The oblong larva is slightly strangulated in the middle, with two rows of rather long thorny horns, the subdorsal ones on the middle segments shorter; green with a large violetish red dorsal spot, broad in front, narrow in the middle, then broad again, and divided into separate spots at the anal end. On various fruit-trees. Evidently imported from Japan or North China to the vicinity of Boston, Massachusetts.

22. Genus: **Epiperola** Dyar.

Antennae of ♂ pectinated almost to the tips; veins 2 and 3 of forewing stalked, the hind tibiae without the middle spurs. *Palaeophobetron* Dyar is synonymous.

Type: *E. drucei* Schs.

E. grandiosa Dgn. (165 i) is a large species with triangular wings and a pointed apex. Forewing choco- *grandiosa*. late brown, warming into yellowish brown towards the costal margin, with a whitish stripe along the submedian fold as far as the margin, somewhat greyer below it and at the margin; a long blackish patch in the

cell. Hindwing brownish black. Metathorax and abdomen orange brown. Expanse of wings: ♂ 39 mm; ♀ unknown. French Guiana.

- drucei*. **E. drucei** Schs. (165 k). Forewing brownish straw-coloured, of a variable tint; a brown slightly bent line from the middle of the inner margin to the apex. Hindwing lighter. Expanse of wings: 25—30, ♀ 32 to 34 mm. Mexico.
- dertosa*. **E. dertosa** Drc. (165 k). Ground-colour of forewing light yellowish, dusted with blackish brown except on the marginal part; a blackish inwardly white-edged line from the middle of the inner margin to the apex, the anal part behind the line scaled orange; a short black, above white streak at the base, a black double dot at the cell-end. Hindwing broadly dusted with blackish. Expanse of wings: ♂ 22—23 mm; ♀ unknown. Colombia.
- paida*. **E. paida** Dyar (= *osseata* Schs.) (165 k) is light straw-coloured, scantily strewn with black, the forewing with a bent white line from the middle of the inner margin to the distal third of the costal margin, edged with dark inside and broadly with light ochreous outside; a small strangulated discal spot at the cell-end. Hindwing more purely light yellowish. Expanse of wings: ♂ 14—15 mm; ♀ unknown. Guatemala, Panama.
- peluda*. **E. peluda** Dgn. (165 k). Forewing stone-grey with a bent white line in the distal third, strewn with black, with small black velvety spots and a faint discal dot. Hindwing light blackish with small marginal spots. Expanse of wings: ♂ 13—18, ♀ 20—23 mm. Costa Rica, Colombia, French Guiana, Brazil (Amazons).
- antelia*. **E. antelia** Drc. resembles *peluda*, but the white line is more incurved below, the area before the line dusted blackish, and behind it at the anal angle there is an extensive area of reddish scales. Hindwing blackish, darker than in *peluda*. Expanse of wings: ♂ 16—17 mm; ♀ unknown. Peru; Bolivia.
- albimarginata*. **E. albimarginata** Kaye (= *argenteolinea* Gaede) is smaller than *antelia*, with darker hindwings. Expanse of wings: ♂ 13—15 mm; ♀ unknown. Panama, Trinidad, French Guiana, Brazil (Amazons).
- archaea*. **E. archaea** Dgn. (165 k). Forewing dusty blackish brown, the ground-colour before the whitish, very undulate line is deeper black. Hindwing dingy, light, more or less dusted blackish. Expanse of wings: ♂ 16 to 19 mm; ♀ unknown. Colombia.
- dyari*. **E. dyari** Dgn. (165 k). Blackish with a slight copper reflection, the line white, incurved below, deeper black before it. Hindwing quite black. Expanse of wings: ♂ 23 mm; ♀ unknown.
- flexilinea*. **E. flexilinea** Dgn. resembles *dyari*, but it is somewhat smaller and probably not different from *dyari*. Expanse of wings: ♂ 18 mm; ♀ unknown. Colombia.
- vafera*. **E. vafera** Drc. (= *gaya* Schs.) (165 k). Forewing blackish, finely and scantily strewn with white, with a white line from the middle of the inner margin to the apex, with a slight doubling before it; base of fringe with a whitish line. Hindwing just as dark with a similar line at the fringe. Expanse of wings: ♂ 20—25 mm; ♀ unknown. Mexico, Guatemala, Panama, Venezuela, French Guiana, Peru, Brazil (Amazons).
- vafinsa*. **E. vafinsa** Dgn. is similar to *vafera*, but dark reddish brown, not blackish and not strewn with white; the line and the margin light, the former not double. Hindwing light black. Expanse of wings: ♂ 24—27 mm; ♀ unknown. Colombia.
- vaferella*. **E. vaferella** Dyar (166 a) is likewise similar to *vafera*, but smaller, not strewn with white, the line single, slightly bent, likewise a white border-line at the base of the fringe. Expanse of wings: ♂ 17—20 mm; ♀ unknown. Costa Rica, Panama, Brazil (Amazons).
- conformis*. **E. conformis** Dyar (166 a) differs from *vaferella* in the distinctly triangular and less broad shape of the wings; the line is light, rather broadly shaded, the white border-line is absent. Hindwing light at the base, darkened outside, contrasting with the forewing. Expanse of wings: ♂ 23 mm; ♀ unknown. Mexico (Colima).
- monochroma*. **E. monochroma** Dyar is quite unicoloured orange or orange brown, without markings; wings rather narrow, the abdomen relatively long. Expanse of wings: ♂ 28—30 mm; ♀ unknown. Panama.
- lagoaphila*. **E. lagoaphila** Dyar (166 a) has light yellowish forewings dusted with dark brown and reddish, the latter colour especially in the basal part of the inner margin; distal margin somewhat widened analwards and here subterminally with 2 black dots on veins 3 and 4. Hindwing light; abdomen long. Expanse of wings: ♂ 22 to 25 mm; ♀ unknown. French Guiana.
- perornata*. **E. perornata** Dyar (166 a). Forewing olive yellow at the apex, the rest of the wing dusted with violetish grey, a white fine line is bordered with black and twice undulated, with reddish colouring behind it analwards; one dentate black spot each at the cell-end and basally; a round violet spot bordered with black above is behind the exterior line before the anal angle. Hindwing blackish, fringe speckled light. Shape of ♂ wings oblong-triangular, that of the ♀ broader and obtuser. Expanse of wings: ♂ 25, ♀ 25 mm. Costa Rica, French Guiana. The type described as a ♂ is in fact a ♀.
- sombra*. **E. sombra** Dyar (166 a) has the same shape of wings as *monochroma*, but it is smaller and less strongly built; quite blackish, the forewing with a light longitudinal stripe through the middle, widening outside,

so that it occupies almost the whole distal margin. Hindwing broadly semidiaphanous in the disc. Expanse of wings: ♂ 22 mm; ♀ unknown. French Guiana.

E. includens Dgn. (166 a). Blackish grey with a broad, somewhat spotted, uniformly bent black line *includens*, extending parallel with the inner and distal margins, a black stripe along the median vein, the area between this stripe and the line dull yellowish. Hindwing blackish. Expanse of wings: ♂ 22 mm; ♀ unknown. French Guiana.

E. arcuata Drc. (166 a). The ♂ is long-winged with small hindwings. Forewing violettish grey, strewn *arcuata*, with black, with a short silvery white streak at the submedian fold, behind which a reddish spot follows before the anal angle; exterior line light brown, blackish spots before it, a dark discal spot at the cell-end. The wings of the ♀ are of a broader and more rounded shape, the colouring is light wood-brown, the markings more prominent though not more distinct than in the ♂. Hindwing blackish, not so uniformly dark as in the ♂. Expanse of wings: ♂ 24, ♀ 25 mm. Mexico.

E. radiata Gaede resembles *Perola solaria* Dogn., but it is smaller, with a white streak on the base of *radiata*, the median vein and in the middle of vein 1; veins 2—5 and 7—8 are white inwardly of the line; no yellowish brightening. Expanse of wings: ♂ 20 mm; ♀ unknown. Bolivia (Rio Songo).

23. Genus: **Perola** Wkr.

As in *Epiperola*, veins 2 and 3 of forewing stalked, distinguished by the presence of both pairs of spurs on the hind tibiae. Synonyms of this genus are: *Amydona* Wkr., *Camila* Wkr., *Romosa* Wkr., *Candyba* Wkr., *Asbolia* Mschlr., *Pseudasbolia* Ky. The genus contains a great number of species.

Type: *P. murina* Wkr.

P. murina Wkr. (= *aequicolor* Gaede) (166 b) is unicoloured dark mouse-coloured, the forewing somewhat *murina*, lustrous, indistinctly irrorated darker. Expanse of wings: ♂ 40—44 mm; ♀ unknown. Brazil.

P. repetita Drc. (166 b) is somewhat smaller than *murina*, blackish mouse-coloured, the forewing finely *repetita*, and uniformly strewn with white scales. Expanse of wings: ♂ 24—36, ♀ 37 mm. Antennae the same in both sexes. Mexico, Central America, Venezuela, French Guiana, Bolivia, Peru.

P. cuneata Strd. is larger than the following *brumalis*, the white line along the median vein extends *cuneata*, to the margin, the distal line above it is strongly bent and encloses at the apex a large brown comma-shaped spot. Expanse of wings: ♀ 58 mm; ♂ unknown. Ecuador.

P. brumalis Schs. (166 b). Dark greyish brown, a white line along the median vein from the base bends *brumalis*, upwards at the cell-end, extends to the costal margin and bifurcates in the upper half; from the apex a white submarginal line extends at first along the margin, then to the middle of the inner margin; the costal-marginal area is darker mouse-coloured, the distal area greyish brown; the median line is edged with reddish bronze. Expanse of wings: ♂ 23—35, ♀ 35—43 mm. Brazil.

P. chica Jones differs from *brumalis* merely in its very light yellowish ochreous colouring and may be *chica*, only a differently coloured form of *brumalis*. Expanse of wings: ♂ 25—30 mm; ♀ unknown. Paraguay, Brazil.

P. cicur Schs. (166 b) is still lighter than *chica*, the white lines and the more variegated ground-colour *cicur*, quite indistinct, the reddish ochreous ground exhibits only the brown borders of the light lines. Expanse of wings: ♂ 30 mm; ♀ unknown. Brazil (Rio de Janeiro).

P. burchelli Dyar. The white line along the median vein bends up to the apex and is not forked, the *burchelli*, costal area is red-brown, the inner-marginal area excepting the base blackish grey. Expanse of wings: ♂ 31 mm; ♀ unknown. Brazil (Goyaz; Lassance, Minas Geraes, in November 1919, Coll. Cornell University).

P. prosper Dyar (166 b). Forewing white, suffused with olive brown, leaving free a broad white sub-marginal band with irregular margins; strewn with white around the cell and at the margin; a dark dot in the base of the cell, a large discal spot at the cell-end. Hindwing whitish. Expanse of wings: ♂ 24—25 mm; ♀ unknown. Brazil (Lassance).

P. bistrigata Hmps. (= *lucia* Schs.). Glossy purple brown with an undulating exterior line; a long black *bistrigata*, streak and a dot in the cell, a small irregular spot below it. Expanse of wings: ♂ 22 mm; ♀ unknown. Santa Lucia.

P. sucia Schs. (= *inscripta* Gaede) (166 b). Forewing lustrous flesh-coloured with irregularly dentate *sucia*, dark lines and 2 small dots in the middle of the distal margin. Expanse of wings: ♂ 28 mm; ♀ unknown. Brazil.

P. jorgenseni Schs. (166 c) is smaller than *sucia*, darker flesh-coloured, both the dark exterior lines fine *jorgenseni*, and more regularly dentate. Expanse of wings: ♂ 20—22 mm; ♀ unknown. Argentina.

- cilipes*. **P. cilipes** Wkr. Mouse-coloured, 2 small white spots on the thorax in front; forewing with 2 round dark spots above the anal angle and a streak below the cell, touching 2 small bent preapical spots. Expanse of wings: ♂ 30 mm; ♀ unknown. Habitat unknown.
- punctata*. **P. punctata** Wkr. (= *aspera* Dgn.) (166 c). Forewing light yellowish with a silky gloss, with a slight flesh-coloured tint; lines very indistinct, the marginal dots somewhat faded, 2 dots before the apex at the costal margin. Expanse of wings: ♂ 20–25 mm; ♀ unknown. Surinam; Brazil.
- subpunctella*. **P. subpunctella** Dyar (166 c) is probably only a smaller race of the following *subpunctata*, for it is merely a little larger. Expanse of wings: ♂ 20–22 mm; ♀ unknown. Paraguay, Brazil.
- subpunctata*. **P. subpunctata** Wkr. (= *micans* Mschl., *sericea* Btlr., *dora* Drc., *guaica* Kaye) (166 c). Forewing yellowish with a silky gloss, of a slight flesh-coloured tint, strewn with black scales, which being accumulated in the centre of the margin form one or two dots, occasionally also a dot near the base of the cell and traces of a distal line. Expanse of wings: ♂ 17–30, ♀ 35 mm. Panama, Venezuela, Guiana, Brazil.
- parallela*. **P. parallela** Dyar (166 c) is of a rather slender build, with narrow and long wings, brownish ochreous, strewn with brown scales, which being accumulated indicate 2 rather indistinct and spotted almost parallel lines; a submarginal row of spots is only distinctly prominent at the veins 2 and 3. Expanse of wings: ♂ 25 mm; ♀ unknown. Brazil.
- brevicornis*. **P. brevicornis** Dyar (166 c). Forewing pointed triangular, reddish violet in the costal-marginal third, light metallic yellow below it, strewn with dark, with an irregularly dentate fine exterior line; two spots at the margin at veins 3 and 4 are connected and form 2 longitudinal streaks. Expanse of wings: ♂ 37 mm; ♀ unknown. Costa Rica.
- nitidissima*. **P. nitidissima** Dgn. (166 c). Like *brevicornis*, but the shape of the wings more quadrangular, not pointed, with a brass lustre, the costal-marginal shadow not contrasting; exterior line undulate; a dark stripe below vein 2 proceeds from the cell. Expanse of wings: ♂ 33–35 mm; ♀ unknown. Peru (Yahuarmayo).
- sinaloensis*. **P. sinaloensis** Schs. (166 d). Dark greyish brown, the forewing with a bent exterior median line, bordered with light outside; the distal area light brownish mouse-coloured. Hindwing dark. Expanse of wings: ♂ 20–23, ♀ 24–26 mm. Antennae of ♀ serrate. Mexico (Sinaloa).
- solaria*. **P. solaria** Dgn. (166 d) is light yellowish, the disc with a slight metallic gloss, strewn with dark, with light veins; the slightly undulated dark fine exterior line is bordered with light towards the margin; a dark spot in the base of the cell and a small yellow spot above vein 1. Expanse of wings: ♂ 23–26, ♀ 28 mm. Peru.
- umber*. **P. umber** Dyar (166 d) is rather dark brown with a slightly bent broad dark line from the costal margin before the apex to the basal third of the inner margin; inner-marginal area dark with a line on the submedian vein; the marginal area is light with dark veins. Expanse of wings: ♂ 23–27, ♀ 30 mm. Antennae the same in both sexes. French Guiana.
- clara*. **P. clara** Dyar (166 d) is dark ochreous with a single bent uniformly brown exterior line. Expanse of wings: ♂ 22–25 mm; ♀ unknown. Mexico.
- rubens*. **P. rubens** Schs. (166 d). Dark reddish ochreous, costal area tinged with pink, with a brown undulate exterior line and fine dark veins. Hindwing of ♂ whitish, fringe dark, of ♀ bronze brown. Expanse of wings: ♂ 23–26, ♀ 27 mm. Brazil.
- danetta*. **P. danetta** Dyar resembles *rubens*, but it has a less concave and less pink-tinged costal margin. Hindwing light ochreous, fringe light. The ♀ shows a broad shaded exterior line. Expanse of wings: ♂ 25, ♀ 38 mm. Paraguay.
- producta*. **P. producta** Dyar (166 d) has narrow, pointed forewings; light ochreous, marked red-brown, with an intensely shaded costal-marginal part; the exterior line extends from the apex to the base, a less distinct submarginal line parallel to it. Hindwing dark orange. Expanse of wings: ♂ 40 mm; ♀ unknown. Costa Rica.
- villosipes*. **P. villosipes** Wkr. Wings shaped as in *producta*, but larger, with an irregular exterior line which is dentiformly bent inward opposite to the cell; costal and inner margins dusted with reddish pink. Hindwing light ochreous with a reddish pink inner margin. Expanse of wings: ♂ 39–47, ♀ 50–63 mm. Costa Rica, Panama, Colombia, Venezuela, Guiana.
- actiosa*. **P. actiosa** Dyar (166 d). Wings broad, the apex not produced, but pointed; dark rusty brown, with dark veins and a line in the cell; two bent brown bands in the distal part, the exterior one unites with a marginal line above the middle of the distal margin, both extending to the base. Hindwing darker brown, less reddish. Expanse of wings: ♂ 30–33 mm; ♀ unknown. Colombia.
- druceoides*. **P. druceoides** Dgn. is lighter than *actiosa*, more yellowish, the two bands less approaching each other, the exterior one finer. Hindwing dark ochreous. Expanse of wings: ♂ 30–32 mm; ♀ unknown. Ecuador.
- laopepe*. **P. laopepe** Dyar (166 e) is larger than *druceoides*, the exterior line indistinct, and double towards the inner margin, the light area between the two lines traversed by a subcostal shadow, so that it looks as if the

wing were alternately traversed by light and dark lines. Expanse of wings: ♂ 33—38 mm; ♀ unknown. Colombia.

P. monomania Dyar (166 e) has yellowish ochreous wings intensely strewn with rusty brown, an irregular line extends from below the cell to the dark-striped subapical veins; the exterior line extends from before the apex to the base and is undulately dentate. Hindwing brownish orange. Expanse of wings: ♀ 43 mm; ♂ unknown. Mexico.

P. benedocta Dyar (166 e) is ochreous with dark-striped veins of the basal area, the sharply dentate exterior line extends near the margin, followed behind by a faint, more curved submarginal line. Expanse of wings: ♂ 35 mm; ♀ unknown. Argentina.

P. paraguaicula Dyar resembles *benedocta*, but it is smaller and darker, more reddish on both wings; the exterior line is more remote from the margin and bends more back towards the inner margin, forming an inward dent opposite the cell; the subterminal line is more distinct and dentate. Expanse of wings: ♂ 30 mm; ♀ unknown. Paraguay.

P. affinis Dyar (166 e) is larger than *paraguaicula*, lighter and more with a silky gloss, with a large whitish spot at the inner margin below the cell; the exterior line bends in towards the cell with a dent, its other course being regular; submarginal line indistinct. Hindwing reddish ochreous, darker than the forewing. Expanse of wings: ♂ 40 mm; ♀ unknown. French Guiana.

P. petropolis Dyar (166 e) resembles *affinis*, the broad light glossy silken marginal area is confluent with the light basal inner-marginal area; exterior line remote from the margin, dentate, the veins inward of it striped brown. Expanse of wings: ♂ 34—40 mm; ♀ unknown. Brazil.

P. regina Dyar (166 e) is larger and lighter than *petropolis*, with greater contrasts, especially the light glossy silken inner-marginal spot is extensive and very distinct. Expanse of wings: ♂ 42 mm; ♀ unknown. Ecuador, Peru.

P. sericea Mschlr. (166 f) shows the light marginal area widened and extending to the cell, the submarginal line more or less interrupted, often reduced to small spots; the basal area is narrow, dusted with brown in the ♂, clear in the ♀, with striped veins. Expanse of wings: ♂ 35—45, ♀ 37—53 mm. Mexico, Central America, Panama, Guiana.

P. degenerans Dyar looks like a small *sericea*, but without their contrasts; distal line spotted, but connected by brown shading; marginal area not lighter. Expanse of wings: ♀ 40 mm; ♂ unknown. San Salvador.

P. sibillanta Dyar (166 f) is dark rusty brown, lighter at the distal and inner margins, the submarginal line obliterated, shaded, the veins within it strongly ruled with lines. Expanse of wings: ♂ 35 mm; ♀ unknown. Brazil.

P. platona Schs. (166 f) is much darker rusty brown than *sibillanta*, the marginal area also uniformly darkened. Hindwing dark red-brown. Expanse of wings: ♂ 36—37 mm; ♀ unknown. Venezuela.

P. invaria Wkr. Dark rusty brown, the wings of a narrower shape than in *platona*, somewhat lighter than *platona*, the ground-colour somewhat more yellowish, the exterior line distinctly prominent, spotted, the veins ruled with dark lines as far as the margin; hindwing more rusty brown. Expanse of wings: ♂ 35 mm; ♀ unknown. Honduras.

P. penumbra Dyar (166 f) is distinguished from *invaria* by its quite chocolate brown colouring, dark, the hindwing suffused with blackish, not reddish. Expanse of wings: ♂ 35—38 mm; ♀ unknown. San Salvador.

24. Genus: **Hepialopsis** Dyar.

Palpi projecting beyond the vertex; veins 2 and 3 of forewing separated. Hind tibiae without middle spurs. Only a single species:

H. agemytha Drc. (166 f) is dark brown with a few irregular, angular silvery markings, an undulated one at the base, 2 submarginal ones, the upper one of which is nearer to the margin than the lower one, and a round discal spot. Hindwing somewhat lighter brown. Expanse of wings: ♂ 22 mm; ♀ unknown. Mexico (Guerrero).

25. Genus: **Narosopsis** Dyar.

The palpi do not reach the vertex, but project beyond the frons, obliquely erect, truncate. Vein 7 of forewing arises from the cell near the origin of 6. Hind tibiae with both the pairs of spurs. Only one species:

N. leucospila Dyar (= *vynia* Schs.) (166 f). White or yellowish white with a light yellowish brown subterminal band which is broadest towards the costal margin; a small black spot near the base, one in the cell and a subapical one in the dark band. Expanse of wings: ♂ 13—15 mm; ♀ unknown. Guatemala, Costa Rica.

26. Genus: **Cryptophobetron** Dyar.

Very closely allied to *Narosopsis*, but vein 6 of hindwing coincides with 7. Likewise only 1 species:

oropeso. **C. oropeso** Barnes (166 g) is a small species looking like an *Alarodia*, excepting the grey colouring. Dark grey, the sexes similar; a postmedian oblique white macular band, triangularly widening inward in the disc. Expanse of wings: ♂ 13—16, ♀ 18 mm. Arizona (Baboquivari Mts., Wenden, Yuma County).

27. Genus: **Heuretes** G. & R.

The ♂ being still unknown, the position is uncertain for the present; antennae of ♀ uncommonly short, ciliated, marked black before the tips. Only 1 species:

picticornis. **H. picticornis** G. & R. Forewing pointed at the apex, monotonously straw-coloured, hindwing whitish. Expanse of wings: ♀ 16 mm. Larva unknown, but the cocoon is of a hard brown tissue, white outside, spun to a leaf. St. Thomas, Virgin Is. Since the only original type, the species has no more been found.

28. Genus: **Leucophobetron** Dyar.

This genus likewise containing but one species differs from *Cryptophobetron* in the presence of vein 6 on the hindwing. The head is small and hidden, the palpi do not project beyond the frontal tuft. ♂ hindwing rounded as in the ♀.

argentiflua. **L. argentiflua** Geyer. White, with a grey spot at the anal angle, the ♂ with another small red spot above it. Under surface white. Expanse of wings: ♂ 20—26, ♀ 24—27 mm. Larva unknown, but DEWITZ describes the cocoon to be of a normal structure.

29. Genus: **Alarodia** Mschlr.

Separated from the preceding genus merely by the stronger head. Synonyms of the genera are: *Phyrne* Grt. nec H.-Schäff., *Calybia* Ky., *Eupoeya* Pack.

Type: *A. nana* Mschlr.

minuscule. **A. minuscule** Dyar (166 g). The ♂ is white without any markings, the forewing beneath smoky, darkest along the costal margin. Expanse of wings: ♂ 11 mm; ♀ unknown. Cuba (Matanzas).

slossoniae. **A. slossoniae** Pack. (166 g). White, the ♀ with a small reddish spot above the anal angle and sometimes another one at vein 6; beneath smoky along the costal margin. Expanse of wings: ♂ 15—17, ♀ 20—23 mm. Larva flat, green, with a series of fleshy horns along the sides, somewhat hollowed out on the dorsum, with more or less distinct crescentiform red spots; on Mangroves. From the Coast of Florida.

pygmaea. **A. pygmaea** Grt. (= *fumosa* Grt.) (166 g). The ♂ is white with a zigzag-shaped red-brown line from the centre of the inner margin to vein 3, and two dots each at the veins 6 and 7; smoky beneath, darkest along the costal margin. The ♀ shows a broad oblique faded, light smoky brownish subterminal band. Expanse of wings: ♂ 12—14, ♀ 20 mm. Cuba (Baracoa).

immaculata. **A. immaculata** Grt. (= *nivalis* Pack., *maculata* Schs.). White, the ♂ with 4—6 short red-brown submarginal streaks from veins 2—5 or 7; the ♀ is without any marking. Under surface without or with but very few dark scales at the costal margin. Expanse of wings: ♂ 12—14, ♀ 14—15 mm. Cuba (Santiago).

nana. **A. nana** Mschlr. (= *jamaicensis* Schs.). Forewing white with a grey shadow along the inner margin, the ♂ with a submarginal row of black splashes from veins 2—5. Hindwing dark smoky grey. Both wings beneath smoky, strongest along the margins. Expanse of wings: ♂ 14, ♀ 17 mm. Jamaica.

30. Genus: **Euphobetron** Dyar.

Like *Narosopsis*, but the erect palpi almost reach the vertex.

Type: *E. cupreitincta* Dyar.

moorei. **E. moorei** Ky. (= *rufotessellata* Moore, *schausi* Dogn.) (166 g). Forewing yellowish with brown lines and spots and 6 transverse spotted bands as far as the cell-end, the subbasal one being darkest; a darker spot at the cell-end itself, and obliquely placed small spots between the veins 2 and 4; light colouring follows behind the undulated submarginal line, the brown marginal area is once more crossed by a light subterminal line. Hindwing scarlet. Expanse of wings: ♂ 20, ♀ 25 mm. Larva brown, with irregular horns laterally, resembling a faded leaf. Venezuela, French Guiana, Brazil.

E. aquapennis Dyar (166 g) resembles *cypris*, but it is somewhat larger, with more oblong wings. The *aquapennis*. median area is broadly lighter behind the cell, the discal dot extinct. Expanse of wings: ♂ 26 mm; ♀ unknown. British Guiana.

E. hydropteris sp. n. (166 g) resembles *aquapennis*, but it is much larger. Expanse of wings: ♂ 33 to *hydropteris*. 35 mm; ♀ unknown. From Costa Rica (Sixola River, in March; Tuis, in May), Schaus & Barnes. Types in the U. S. National Museum.

E. cypris Grt. (166 g). Forewing tinged with lilac at the base, a large spot from the centre of the cell *cypris*. almost the margin is lighter, shaded brown in its inner-marginal half, bordered by an undulating white line; a brown band in the distal third of the costal-marginal part is as broad as the narrow marginal area, which is dark brown dusted with red; discal dot rather distinct. Hindwing scarlet; Expanse of wings: ♂ 25, ♀ 33 to 37 mm. The larva was bred by JORGENSEN, but not described. Paraguay.

E. albiplaga Her. & Hopp differs from the following *natadoidea* in a purely white spot on the hindwing *albiplaga*. covering the exterior half of the cell and the basal halves of the veins 1—4; the red area above the middle of the inner margin is small and narrow. The light dentate subterminal line shows a dent before the apex. Expanse of wings: ♀ 30 mm; ♂ unknown. Brazil (Tonantins, Amazons).

E. natadoidea Dyar (166 h) is dark rusty brown with two dark purple grey spots, one at the base, cut *natadoidea*. by an oblique lighter line, and a subapical one traversed by a line in the reverse direction, so that both terminate near together at the costal margin. Hindwing bronze black, fringe light. Expanse of wings: ♂ 24 mm; ♀ unknown. Brazil (Paranapanema, São Paulo).

E. pullum Her. & Hopp. Forewing almost monotonously blackish brown, finely strewn with bluish *pullum*. white, and with a small round dark discal spot; a distinctly defined area in the distal half of the inner margin and at the anal angle is of a brighter brown; a small white blotch behind the lower cell-angle. Hindwing dark brown, fringe light. Expanse of wings: ♂ 27, ♀ 32 mm. Peru, Ecuador. The ♂ type may belong to the genus *Isochaetes*; the ♀♀ may be wrongly ranged here, I did not examine any good specimens.

E. cupreitincta Dyar (166 h) is blackish brown, with a slight bronze reflection, the forewing with in- *cupreitincta*. distinct black undulating lines; subterminal line uniformly dentate, parallel to the margin; a large light yellowish spot behind the cell down to vein 2, an extensive copper-red area, rarely blackish, is in the middle of the inner margin. Hindwing rather dark, dusty blackish. Expanse of wings: ♂ 18—22, ♀ 25—30 mm. Guatemala, Costa Rica, Colombia, Venezuela, Guiana, Brazil (Amazons).

31. Genus: *Isochaetes* Dyar.

Palpi projecting beyond the vertex, the last joint half the length of the long 2nd joint. Forewing with separately arising veins 2 and 3. Hind tibiae with both the pairs of spurs.

Type: *I. beutenmuelleri* H. Edw.

I. beutenmuelleri H. Edw. (166 h). ♂ light tan-coloured, marbled with brown, with a round postcellular *beutenmuelleri*. spot, very conspicuously bordered with violettish grey. Hindwing shaded brown, fringe light. ♀ intensely dusted with violettish grey, similarly marked, with a light spot at the costal margin. Hindwing blackish, fringe light. Expanse of wings: ♂ 12—16, ♀ 17—19 mm. Larva purely grass green, with a series of long, feather-like, glassy horns on each side; it lives on the higher branches of oaks. New York, Maryland, North Carolina, Florida.

I. rufescens Schs. (= *mexicanum* Her. & Hopp) (166 h). ♂ light tan-coloured as in *beutenmuelleri*, the *rufescens*. wings more pointed, more irrorated with brown, the bent light area at the cell-end with an interior dark line, but not a round spot. Expanse of wings: ♂ 17 mm; ♀ unknown. Mexico, Guatemala.

I. marina Dyar (= *cupreitincta* Her. & Hopp nec Dyar) (166 h). Forewing of ♂ dark reddish brown *marina*. strewn with bluish scales, the marking more distinct than in the ♀; the centre of the wing is traversed by an indistinctly defined yellowish band, a dentate dark shadow before it and a dentate dark line behind it; a light elliptical postcellular area is filled with brown, a double light spot is between veins 3, 4 and 4, 5. the same in the ♀; irregular light spots at the margin. Hindwing blackish brown. The ♀ is intensely dusted with dark violettish grey and strewn with blue scales, a dark streak at the cell-end and an exterior brown line, excurved around the cell-end and enclosing a light curved area behind the cell; the wing on the whole dark with obliterated markings. Expanse of wings: ♂ 21, ♀ 22—24 mm. French Guiana, Brazil.

I. ashtabel Dyar (166 h) has dark purple brown forewings, with red-brown spots in the basal area, a *ashtabel*. black acutely angled zigzag line in the middle, bordered with red-brown outside and forming a deep indentation below the median vein; a dark exterior line excurved around the cell-end encloses a curved light area at the cell-end, oval in the upper half, darkened except two whitish spots below. Hindwing bronze black. Expanse of wings: ♂ 18, ♀ 26 mm. British Guiana. Paraguay.

hahneli. **I. hahneli** Her. & Hopp resembles *ashtabel*, but the angled line is only flatly indented in the submedian area. Expanse of wings: ♂ 20 mm; ♀ unknown. Brazil (Amazons). A smaller specimen, not very well preserved, is before me from Santarem (Amazons).

32. Genus: **Phobetron** Hbn.

Palpi much shorter, not reaching the frontal tuft, head small and hidden, in which the genus differs from the allied *Alarodia*. Both sexes very dissimilar, the ♂ with triangular hindwings. Synonyms are: *Ecnomidea* Westw., *Spirocera* H.-S., *Euryda* H.-S., *Nemeta* Wkr.

Type: *Ph. pitheciun* Abb. & Sm.

hipparchia. **Ph. hipparchia** Cr. (= *coras* Stoll, *variolaris* H.-Schäff., *bifacies* Wkr., *basifusca* Wkr.) (166 h). ♂ small, with narrow forewings and a hyaline area in the disc, the markings of the ♀ covered with blackish; hindwing triangular, black, hyaline in the disc. ♀: the reddish ochreous ground marked with violettish grey lines, encircling roundish spots in the cell, 2 below it and 4 behind it, separated by the veins, and at the apex. Hindwing red, dusted blackish in the disc. Expanse of wings: ♂ 23–30, ♀ 18–36 mm. The larva resembles a dry leaf, with subdorsal rows of fleshy, hairy horns of variable length. On different forest-trees. Mexico, Panama, Ecuador, Colombia, Venezuela, Guiana, Brazil, Argentina.

pitheciun. **Ph. pitheciun** Abb. & Sm. (= *abbotana* Hbn., *nigricans* Pack., *hyalinus* Walsh, *tetradactylus* Walsh, *nondescriptus* Wetherby) (166 h). ♂ with narrow and pointed forewings, the basal part with the markings of the ♀, but extensively hyaline in the disc, so that only a dark discal dot and dark scales in the basal part and at the margins remain. The triangular hindwing is black at the costal and inner margins, hyaline in the disc. The ♀ has a dull yellowish ground-colour with blackish brown markings bordering on the lighter spots: a confluent spot in the cell and two below it, dusted blackish behind it, so that the light ground is divided by finger-shaped stripes between the veins. Apex dark with light dusting, marginal line light. Hindwing dusted blackish on the red-brown ground with a light marginal line. Expanse of wings: ♂ 15–20, ♀ 17–25 mm. The larva, like that of *hipparchia*, resembles a faded leaf and lives on various trees in forests and shrubs. Massachusetts, Connecticut, New York, Ohio, Virginia, Florida.

dyari. **Ph. dyari** B. & Benj. The ♀ has the same forewings as *pitheciun*, but red hindwings, the ♂ is still unknown. Expanse of wings: 20 mm. Texas.

33. Genus: **Vipsorola** Dyar.

Like *Euphobetron*, but vein 7 of the forewing is stalked with 8 and 9. Only 1 species:

semivitre. **V. semivitre** Schs. (166 i). Body robust, black; forewing pointed, hindwing quadrangularly cut off at the distal margin. Disc of forewing extensively covered with very scanty scales, the margins more densely blackish. Hindwing except the margins quite hyaline, the black inner-marginal area broadly black. Expanse of wings: ♂ 17 mm. The still unknown ♀ probably looks very different. Guatemala.

34. Genus: **Ulamia** Mschlr.

The ♂ antennae are distinguished by broad, lamellate unilateral pectinations. The veins differ little from those of the allied genera. Only 2 species:

Type: *U. dolabrata* Stoll.

dolabrata. **U. dolabrata** Stoll (= *whitelyi* Drc.) (166 h). A large, robust species, the wings lustrous and wrinkled, brownish yellow, the forewing shaded dark brown from the base to beyond the middle. Hindwing of ♂ tinged pinkish brown only along the inner margin, entirely pinkish brown in the ♀. Expanse of wings: ♂ 35–42, ♀ 53 mm. Venezuela, Guiana, Peru, Bolivia.

sericea. **U. sericea** Schs. (166 i) differs from *dolabrata* in its dark shading in the disc and subterminally. It may not be specifically separated from *dolabrata*. Expanse of wings: ♂ 33–47 mm; ♀ unknown. Peru and Bolivia.

35. Genus: **Tanadema** Dyar.

Distinguished from *Ulamia* by the staff-like single, not double pectinations of the ♂ antennae.

Type: *T. mas* Dyar.

incongrua. **T. incongrua** Dyar (166 i). Basal area of ♂ forewing dark reddish brown, purple brown at the apex, separated from the main colouring by an oblique lilac line. Hindwing blackish. ♀ not yet known. Expanse of wings of the ♂: 18–23 mm. Guiana, Brazil (Amazons).

T. nora *sp. n.* (166 i). Rather light rosy tan-coloured with quite indistinct markings. Hindwing dark reddish brown. Expanse of wings: ♂ 16 mm; ♀ unknown. West Colombia (at the junction of the Rio Tamana and Rio San Juan, 405 ft., February 1909). Types: 2 ♂♂ in the Coll. DOGNIN, U. S. Nat. Museum.

T. peruviana *Her. & Hopp* resembles *mas* *Dyar*, but with quite obliterated markings on the forewing. Expanse of wings: ♂ 16 mm; ♀ unknown. South-Eastern Peru; Brazil (Amazons).

T. marginepunctata *Her. & Hopp* has wood-brown forewings and slightly darker hindwings; forewing with distinct undulating lines and a series of small black marginal dots. Expanse of wings: ♂ 17 mm; ♀ unknown. Colombia.

T. neutra *Dyar* (166 i) is a rather large species, tan-coloured with distinct undulatingly dentate lines. Expanse of wings: ♂ 14—17, ♀ 20 mm. Guatemala, Costa Rica.

T. rubra *Her. & Hopp*. Forewing dark ochreous with distinct dark lines, the hindwing and the under surface carmine. Expanse of wings: ♂ 18 mm; ♀ unknown. Brazil (Rio Madeira).

T. mas *Dyar* (166 i) has violettish red forewings with very distinct dentate lines. Hindwing somewhat browner. Expanse of wings: ♂ 16—17, ♀ 19—20 mm. French and British Guiana.

T. foemina *Dyar* (166 i) is somewhat smaller than *mas* and of a more rosy tinge, perhaps not specifically different. The expanse of wings stated in the original description (10 mm) is a mistake; it is 14—15 mm in the ♀; the ♂ is unknown. French Guiana.

36. Genus: **Dichromapteryx** *Dyar*.

Like the preceding ones, but with unilaterally dentate antennae of the ♂.

Type: *D. dimidiata* *Dyar*.

D. dimidiata *Dyar* (166 k). Forewing dark brown at the base, bordered by an oblique line from the centre of the costal margin to the anal angle, the space behind it lilac whitish, shaded with brownish towards the apex; small double discal dots at the cell-end. Hindwing dark greyish brown. Expanse of wings: ♂ 21—24, ♀ 30 mm. French Guiana.

D. ultima *Dyar* (166 k) has a dark chocolate brown basal half of the forewing, then a straight whitish line, behind it purple brown, rather dark, dusted with the basal colour at the apex. Expanse of wings: ♂ 18 to 20 mm; ♀ unknown. The habitat of the type is not mentioned, but a specimen from Sao Paulo de Olivença (Amazons) agrees well with it.

D. obscura *Dyar* (166 k). Basal area dark brown, apical part lighter, the two colours separated by an oblique light line. Expanse of wings: ♂ 17—20 mm; ♀ unknown. Guiana.

D. didyma *Dyar*. Like *ultima*, but with more violettish brown wings. Expanse of wings: ♂ 18—20 mm; ♀ unknown. Guatemala, Costa Rica.

37. Genus: **Pseudovipsania** *Dyar*.

Antennae of ♂ plain, somewhat flattened; palpi thrice as long as the head, erect in the ♂, straightly porrect in the ♀, with an obtuse terminal joint. The ♂ is without the middle spurs on the hind tibiae.

Type: *P. frigida* *Schs.*

P. frigida *Schs.* (166 k) has dull lilac forewings with an undulating olive brown line from near the apex to the base at the submedian vein, the line more or less bordered with yellow. Hindwing dark lilac brown, with a pink basal tinge. Expanse of wings: ♂ 28—29 mm; ♀ not known. Mexico.

P. invera *Dyar* (166 k). The ♂ has 2 spurs on the hind tibiae, the ♀ 4. Forewing of ♂ narrow and pointed, broad and rounded in the ♀. Wings rather scantily scaled, yellowish flesh-coloured, strewn with black, pinkish brown at the base, shaded dark along the costal margin; the fine submarginal line is distinct, another one inwardly of it is traceable. Hindwing yellowish, pinkish red at the inner margin in the ♂, entirely pinkish red in the ♀. The total impression is that of a *Megalopygida*, such as *Podadia xinga* *Dogn.* or *omayena*, but the neuration of the hindwing proves it to be certainly a *Limacodida*. Expanse of wings: ♂ 25—27, ♀ 32—34 mm. French Guiana.

38. Genus: **Vipsania** *Drc.*

Separated from the preceding genus by the presence of both pairs of spurs on the hind tibiae also in the ♂.

Type: *V. anticlea* *Drc.*

V. bicolor *Her. & Hopp*. Margin of forewing from before the apex to the anal angle bright yellowish, the rest of the wing brown. Hindwing yellowish brown. Expanse of wings: ♂ 25 mm; ♀ unknown. Ecuador.

- anticlea*. **V. anticlea** Drc. (166 k). Forewing dark red-brown with striped veins; an oblique line and a subterminal bent line meet at the costal margin before the apex, the interior line is connected with the base by a dark streak on the submedian fold. Hindwing blackish except the costal margin and fringe. Expanse of wings: ♀ 22—26 mm; ♂ not yet known. Mexico, Guatemala.
- schevi*. **V. schevi** Schs. (166 k) is similar to *anticlea*, somewhat smaller and lighter, more yellowish, especially on the prothorax, the ♂ lighter than the ♀. Hindwing yellowish, reddish pink along the inner margin, and with dark veins. Expanse of wings: ♂ 16—18 mm; ♀ 23 mm. Mexico. Perhaps not to be separated specifically from *anticlea*.
- cacagamelia*. **V. cacagamelia** Dyar is larger than the ♂ of *schevi*, but similar; ground-colour of forewing lighter, not passing into yellowish at the costal margin. Expanse of wings: ♂ 22—25 mm; ♀ not known. Mexico. It may be the ♂ of *rosabella*.
- rosabella*. **V. rosabella** Dyar (167 a). Thorax and forewing yellow, the veins only partly striped dark, the lines fine, light brown, filled with rosy between them. Hindwing yellow, the larger basal half dusted with pink. Abdomen rosy red. Expanse of wings: ♀ 26—29 mm; ♂ unknown. Mexico; Guatemala.
- unicolor*. **V. unicolor** Dyar (167 a). The long porrect palpi are black, with red-brown scales outside and on the terminal joint. Wings black, forewing lustrous and wrinkled; both wings with a fine whitish line at the base of the fringe. Expanse of wings: ♀ 34—36 mm; ♂ unknown. Venezuela, Brazil (Santarem).
- schultzei*. **V. schultzei** Her. & Hopp resembles the following *melanois*, but the forewing is more brownish, the inner margin and fringe pink, the legs rusty brown. Expanse of wings: ♂ 23 mm; ♀ unknown. It may be the ♂ of *unicolor*. Colombia.
- melanois*. **V. melanois** Dyar (167 a). Black, semidiaphanous in the disc of both wings. Collar and anal tuft more or less yellow and pink, anterior hips yellow. Expanse of wings: ♂ 22—26 mm; ♀ unknown. Costa Rica, Panama.

39. Genus: **Microphobetron** Dyar.

Antennae of ♂ plain, somewhat flattened; palpi of normal length, erect in both sexes, slender, smoothly scaled, with a small terminal joint. Wings long and narrow, pointed.

Type: *M. rebella* Dyar.

- rebella*. **M. rebella** Dyar (167 a). A small species with rather long wings. Black, with a faint copper reflection on the forewing. Expanse of wings: ♂ 11 mm; ♀ not known. Costa Rica.
- aenea*. **M. aenea** Her. & Hopp. Forewing bright copper bronze, darker in the cell and in the basal inner-marginal area. Hindwing yellowish white, scantily strewn with black. Expanse of wings: ♂ 17 mm; ♀ unknown. Brazil.

40. Genus: **Claphidia** Dyar.

Separated from the preceding genus by stouter palpi with a distinct terminal joint. Shape of wings triangular; vein 10 arises from the cell, very near to the stalk of 7—9.

Type: *C. microstigma* Dyar.

- microstigma*. **C. microstigma** Dyar (167 a). Basal area of forewing black, with an irregularly roundish border, more yellowish towards the inner margin, strewn with black; distal part grey, densely strewn with black in the shape of indistinct undulating lines; a round white spot in the dark basal area on the submedian fold. Hindwing dusted black with darker veins. Expanse of wings: ♂ 23 mm; ♀ unknown. Bolivia (Buena Vista).
- tersula*. **C. tersula** Drc., according to the description, resembles *microstigma* and may not be specifically different, but considerably larger. Expanse of wings: ♂ 30 mm; ♀ not known. From Peru.

41. Genus: **Venadicodia** Dyar.

Separated from *Claphidia* by the different shape of the wings; forewing not triangular, but the costal and inner margins almost parallel; veins 7—10 on the wing are stalked.

Type: *V. albipuncta* Schs.

- albipuncta*. **V. albipuncta** Schs. (167 a). Forewing brownish grey with a small dark spot at the apex, basal area dark from the costal margin to the submedian vein with a round white dot in it. Hindwing blackish brown. Expanse of wings: ♂ 14—15 mm; ♀ unknown. Mexico (Venadio, Sinaloa).
- ruthaea*. **V. ruthaea** Dyar (167 b). Forewing brownish with a dark brown basal area, bordered by a darker oblique line from before the centre of the costal margin to the inner margin behind the middle, with somewhat whitish scales in the irregular exterior border; distal area light brown with a small brown apical spot which is narrowly continued along the margin. Hindwing blackish brown. Expanse of wings: ♂ 18 mm; ♀ unknown. Habitat not mentioned.

V. denderia Dyar (167 b) is of a stronger build; the basal area of the forewing bordered by an oblique line from the middle of the costal margin to the anal angle, purple brown, marbled lighter, yellowish brown at the apex with a clouded preapical spot. Hindwing blackish. Expanse of wings: ♂ 22—23 mm; ♀ unknown. Costa Rica.

42. Genus: **Vipsophobetron** Dyar.

Separated from *Microphobetron* by the normal triangular shape of the wings. Only 2 small species:

Type: *V. marona* Dyar.

V. marisa Drc. has blackish forewings, the middle area lighter, shaded with reddish violet at the base and distal margin, bordered by thick, somewhat indistinct lines; subterminal line monotonous, basal area spotted. Hindwing blackish. Expanse of wings: ♂ 12—13 mm; ♀ unknown. Panama, Colombia.

V. marona Dyar (167 b) resembles *marisa*, but the whole wing is dusted with dark reddish violet, so that the markings are but faintly visible. Expanse of wings: ♂ 12 mm, ♀ 19 mm. French Guiana.

43. Genus: **Semyra** Wkr.

♂ antennae bipectinate almost to the tips; palpi projecting beyond the vertex, the last joint not quite half the length of the middle joint. Hind tibiae with both pairs of spurs.

Type: *S. coarctata* Wkr.

S. zinie Dyar (167 b). Forewing with a dark basal area bordered by a fine light line which bends at the inner margin to the base; towards the apex 3 angular dark spots border on a light reddish violet quadrangle; marginal area light brown; a distinct silver marking at the base, coherent and lobate. Hindwing light brown. Expanse of wings: ♀ 24 mm; ♂ not known. Paraguay (Sapucay).

S. cardia Schs. (167 b). Forewing pinkish brown, with blackish longitudinal stripes, and red stripes behind the subbasal line and cell; the zigzag-shaped subbasal line is silvery, the light subterminal line fine, irregularly undulated. Hindwing straw-coloured. Expanse of wings: ♂ 20—23 mm; ♀ unknown. Brazil (Castro, Paraná).

S. eucharista Dyar (167 b). Forewing red-brown with a blackish stripe in the cell and a submedian one extending to a light median line which forms inwardly an angle on the submedian vein; the subbasal silvery line is fine and punctiform, some red colouring behind it; a short white line in the brown apical part, a wedge-shaped brown marking below it is divided into 2 or 3 small finger-shaped spots. Hindwing reddish, fringe brown. Expanse of wings: ♀ 24 mm; ♂ unknown. Brazil.

S. erna Dyar has the same markings as *eucharista*, but darkened, the silver marking more distinct. Hindwing brown, sometimes lighter in the disc. Expanse of wings: ♂ 17—19 mm; ♀ unknown. Paraguay.

S. ornata Dgn. (167 c) has the same scheme of markings as *eucharista*, but the median line is dark brown, not dentate on the submedian line, more extensive apical markings, the subbasal silver distinctly divided into single spots. Expanse of wings: ♀ 27 mm; ♂ not known. Brazil (Rio Maués, Amazonas).

S. phrygia Dyar (167 c) is dark brown, without a light median line, the silver mark long and narrow, undulate, some red behind it; the dark subterminal area is divided into spots by light colouring entering finger-shaped; a wedge-shaped discal spot at the cell-end. Hindwing greyish brown, light in the disc. Expanse of wings: ♂ 23 mm; ♀ unknown. Brazil (São Paulo).

S. paula Dyar is similar to *phrygia*, but smaller, of a brighter colouring, with a narrower cellular spot. Expanse of wings: ♂ 18 mm; ♀ unknown. Peru.

S. frances Dyar (167 c); like *paula*, but still smaller, the markings more indistinct, less defined. Expanse of wings: ♀ 17—18 mm; ♂ unknown. Argentina.

S. gibbosa Sepp. Basal half of forewing dark brown with 2 red stripes, outwardly bordered by a fine white line; distal half of the wing light brown with a long dark brown streak from the apex and one from the anal angle. Expanse of wings: ♀ (?) 28 mm; ♂ unknown. The larva has the shape of a small triangular box, dorsally green, laterally light bluish green. Surinam. The species is only known from SEPP's figure which HERING and HOPP (Iris XLI, p. 173, 1927) declare to represent a *Semyra*.

S. coarctata Wkr. (167 c). Brown or greyish brown, the basal half darker, the distal half light, the two colours separated by a light, somewhat curved line; a light lilac spot at the apex is surrounded by quadrangular dark spots, and from here a series of small dots extend more or less distinctly downward. Hindwing from dark brown to blackish brown. Expanse of wings: ♂ 20—22, ♀ 25—27 mm. The northernmore form: — **finita** Wkr. (= *möschleri* Schs.) is lighter and more contrasting than the southern *coarctata*, the submarginal dots are more distinct and extensive, with some red colour behind the basal silver. There are apparently no specific differences. Mexico, Central America, Panama (*finita*); Guiana, Grenada, Paraguay, Brazil (*coarctata*).

- irena*. **S. irena** Dyar (167 c) is much larger than *coarctata*, the lighter parts wood-brown, the apical quadrangular subterminal spots distinctly separated, without a prolongation downward. Expanse of wings: ♂ 29—32, ♀ 36—37 mm. Panama, Guiana, Peru.
- bella*. **S. bella** H.-Schäff. (= *gladys* Dyar) (167 c) shows an indistinct light partition-line between the basal and distal halves, the subbasal silver as narrow as a thin thread, often quite extinct, a large red spot behind it; a lilac apical spot is encircled by 3 dark spots, cut by a dentate silvery line, a roundish clouded spot before the anal angle. Expanse of wings: ♂ 26 mm; ♀ not known. Panama, Colombia, Trinidad.
- distincta*. **S. distincta** Mschlr. is darker than *bella*, the subbasal red colour replaced by dark brown. Expanse of wings: ♂ 25—27, ♀ 30—34 mm. Central America, Guiana, Bolivia.
- lucilla*. **S. lucilla** Dyar (167 d) has the same markings as *bella*, but the whole wing is dark purple brown, the spots distinct, but not contrasting. Hindwing brownish black. Expanse of wings: ♂ 25 mm; ♀ unknown. Venezuela.
- mariae*. **S. mariae** Dyar (= *veterna* Dgn.) (167 d) likewise resembles *bella*, but it is entirely blackish brown, only the subapical lilac spot is traceable, sometimes also the subbasal red visible. Expanse of wings: ♂ 20 to 26 mm; ♀ unknown. Guiana, Brazil (Amazons).

44. Genus: **Prolimacodes** Schs.

Characterized by biserrate antennae of the ♂. Rather large species of a compact structure, otherwise not differing much from the allies.

Type: *P. triangulifera* Schs.

- polygona*. **P. polygona** Her. & Hopp has a dark blackish brown costal-marginal area extended downward into 3 somewhat quadrangular lobes which are separated from the light brown inner-marginal and distal-marginal areas by a silvery white line. Only the ♀ is known. Expanse of wings: 25 mm. Mexico (Cordoba).
- triangulifera*. **P. triangulifera** Schs. (167 d) shows the dark brown costal-marginal area brightened towards the costa, of an oblong, below rounded shape, outwardly somewhat concave, likewise separated from the other light brown part of the wing by a silvery white line. Expanse of wings: ♂ 28—32, ♀ 35—40 mm. Mexico, Guatemala, Costa Rica, Panama.
- lilalia*. **P. lilalia** sp. n. (167 d) like *triangulifera* shows rather long wings, the dark costal spot uniformly dark, not lighter above, convex outside, bordered by a silvery line. Inner-marginal area light brown, slightly strewn with silvery scales towards the base. Hindwing triangular, distal margin straight. Expanse of wings: ♂ 32 mm; ♀ not known. 1 ♂ from French Guiana (St. Jean, Maroni R.), March 1904 (W. SCHAUS); type in the U. S. National Museum at Washington.
- dividua*. **P. dividua** Dyar (167 d) has a more quadrangular dark costal-marginal spot, the edges undulately denticulate; interior area light brown, the basal angle occupied by a large silvery area which is strewn with brown along the inner margin. Expanse of wings: ♂ 26—28 mm; ♀ unknown. Mexico (Cuernavaca).
- trigona*. **P. trigona** H. Edw. (167 d). Costal-marginal area light brown, gradually passing over to the lighter inner-marginal area, or also separated by an indistinct darker line: — **telligii** Barnes (= *filifera* Dyar); a large silvery spot at the base vanishing more or less along the indistinct partition-line of the two colours. Expanse of wings: ♂ 28—30, ♀ 32 mm. Arizona.
- undifera*. **P. undifera** Wkr. (= *apsorrhia* Dyar, *scaphoides* Her. & Hopp) (167 e). Costal-marginal area dark brown, uniformly bent below, only basally with a deep incision, inner-marginal area light brown, scantily strewn with black; the silvery scales bordering on the costal-marginal spot below, are accumulated at the basal end forming a somewhat diffuse silvery spot. Expanse of wings: ♂ 30—34, ♀ 32—38 mm. Mexico, Honduras, San Salvador, Guatemala, Costa Rica, Colombia.
- badia*. **P. badia** Hbn. (= *scapha* Harr.) (167 e) resembles *undifera*, but it is smaller; the form: — **argenti-**
argentimac-
cula. **macula** B. & McD. shows the silver scaling at the basal angle of the costal-marginal spot enlarged and more intense. Expanse of wings: ♂ 22—25, ♀ 25—31 mm. The larva has the shape of a triangular small box with impressions as in the shell of a tortoise, green, more or less spotted brown or not at all, pointed at the anal end. On various trees in forests. Massachusetts, New York, and to the south as far as Florida.

18. Family: Epiplemidae.

The uncertainty concerning the position of this group makes it also very difficult to insert its elaboration in the various volumes of the "Macrolepidoptera". While older authors combined it with the *Uraniidae*, other species ranged here could be ascertained to be allied with the *Geometridae*. Later on, when these combined species proved to be no *Epiplemidae* at all and to have been classified with them only by mistake, one fell back to emphasizing these relations to the *Uraniidae*. In general, the systematizers who confined themselves to examining one criterion have arrived at very different results. KIRBY's Catalogue, while inserting the *Uraniidae* — perhaps not wrongly — between the *Coccytiidae* and *Agaristidae* both being groups with certain relations to the large Noctuid family, does not mention the *Epiplemidae* at all in the volume containing all the Macroheterocera except the *Geometrids* and *Noctuids*; thus, it seems, KIRBY has found the *Epiplemidae* to be in no way connected with any of the families enumerated in his Catalogue, nor with the *Uraniidae*. HAMPSON derives the *Uraniidae*, *Heterogynidae*, *Cossidae* etc. from the *Zygaenidae*, and from the *Uraniidae* on the one hand the *Notodontidae*, on the other hand the *Geometridae* (and as third the *Ceratocampidae* as the forerunners of the Saturnid group); in this case, the *Uraniidae* sens. ang. would probably form the transition to the *Notodontidae*, and the *Epiplemidae* to the *Geometridae*. In his enumeration the *Uraniidae* follow upon the *Sematuridae* which he separates from them. Considering such uncertainty it is of no great importance where the *Epiplemidae* have been placed; it is at any rate not our task to establish new systems, we are merely guided here by perspicuity; the general characters of the *Epiplemidae* may be read over again in Vol. II, p. 277, Vol. X, p. 93 and 577, and Vol. XIV, p. 390.

Proboscis and frenulum present. Vein 5 in both wings arises from the middle of the cross-vein or above it. Veins 6 + 7 of the forewing are usually stalked, 7 being at any rate widely separated from vein 8. Vein 8 of hindwing from its beginning arises freely from the base. Concerning single peculiarities and habits, we refer our readers to all the necessary details mentioned in Vol. X (p. 577) and Vol. XIV (p. 387), where we have also mentioned the hair-case on the hindwing of *Er. birostrata* Gn. from South America.

As in the Old World, there are also in America but few species occurring in the temperate zone. In the tropical regions, Peru seems to be relatively rich in species. As in the Indo-Australian Fauna, the genus *Epiplema* contains an excessive number of species compared with the other genera. The species have been known for a very long time, WALKER having already described a considerable number of them, though of course many synonyma may be among them. By far the most of the species have been described by WARREN as in the Indo-Australian Fauna, too. Owing to the kindness of Dr. JORDAN who placed illustrations of them at our disposal, we are now able to present a great part of WARREN's types. Without this assistance it would be futile to treat this family. Both the author and the readers of this work are therefore greatly indebted to Dr. JORDAN. The work has also been aided by the kind information of Mr. W. H. TAMS of the British Museum. Most of the genera contain only American species; in the few species represented also in other faunae, this fact has been mentioned. In the present volume, as well as in the African and Indo-Australian Faunae, the *Epiplemidae* are separated from the *Uraniidae*, in accordance with modern views. By reason of the tympanal organs on the abdomen being the same in both the groups, SICK now states (in the Verhandl. Deutsch. Zool. Ges., Vol. 37) that both are to be united again as formerly. We cannot argue here whether it is appropriate to take such a decision merely from this one organ.

1. Genus: **Decetia** Wkr.

This genus, like the whole family of *Epiplemidae*, is difficult to define, and some palaearctic species have been branched off as a separate genus (*Mimozethes* Warr.) and enumerated as *Drepanidae* (cf. Vol. II, p. 196). In the supplementary to Vol. II *Mimozethes* has been placed to the *Epiplemidae* (p. 172). The genus being represented by 17 forms in the Indian Region was more largely dealt with in Vol. X, p. 580, where a number of species are figured on pl. 58 e. The resemblance of the habitus to that of some *Drepanidae* is evident. — Palpi short. Antennae of ♂ with one row of pectinations. Forewing broad with a pointed apex, shortly

excavated below it. Vein 5 above the middle of the cross-vein. 6 + 7 and 8 + 9 stalked, 11 terminating into 12. Type = *numicusaria* Wkr. from India (Vol. X, pl. 58 e).

accipiteraria. **O. accipiteraria** Wkr. Reddish yellow, dusted brown. Forewing with 2 hardly recognizable interior lines. A broad violettish brown line from the apex, distinct outside, faded inside. A few black submarginal dots. The apical line of the forewing will probably be continued on the hindwing. 36 mm. Venezuela.

D. minimaria Wkr. was placed here by DALLA TORRE, but it is presumably no *Decetia* and no *Epiple-mida* at all.

2. Genus: **Aorista** Warr.

This genus was established by WARREN for a single species described by DOGNIN from Loja, exhibiting a strange resemblance to the *Urapteroides* which are reckoned to the *Microniinae* and otherwise unknown in the American Fauna. On comparing the American *Aorista* with *Urapteroides urapterina* figured in Vol. X on pl. 72 a, we find it to look almost exactly like a smaller sized specimen of this Australian species. Not only the black-spotted marginal dent of the hindwing seems to be exactly copied in the two species which are geographically so distantly separated, but also the course of the oblique line traversing the wings is the same, and another remarkable fact is that the costal-marginal edge of *Aorista* exhibits the very same deep black transverse streaks which are so conspicuous in numerous *Microiinae* of the Indo-Australian Region, as for instance in *Stesichora advocataria* Gn. (Vol. X, pl. 72 f) and others. — The type of this scheme of marking is also repeated in quite different families on both hemispheres, e. g. in the *Asthenidia* in America and the *Urapteryginae* of the Old World. This zoogeographical curiosity reminds us also of the analogous phenomenon in the distribution of the genuine *Uraniidae*, where the genus *Chrysiridia* in South-East Africa is separated from the *Urania* in South America by oceans and continents showing no connection whatever. — A less unintelligible though remarkable fact is that this type of colouring is also exhibited by other genera of South American *Epiplemidae*, as for instance by *Morphomima albipennaria* H.-Schäff. (170 e). — Palpi short. Antennae of ♂ short, pectinated. Forewing broad, apex slightly produced, distal margin oblique. Vein 5 from the upper cell-angle, 6 + 7 and 8 + 9 + 10 stalked. Vein 11 terminating into 12 and 10 into 11. Veins 3 + 4 and 6 + 7 of hindwing stalked, 5 a little above the middle of the cross-vein. Broadly projecting at the margin between veins 3 and 4, a point at vein 2, then two excisions at the anal angle. Type and only species:

alodia. **A. alodia** Dgn. (170 a). Wings milky white. Forewing striated brown at the costal margin, with 4 transverse lines coloured like coffee with milk, the second of which is most distinct, while the third may even be absent. Hindwing with 3 lines which are confluent at the lobe at veins 3 and 4, where they terminate in streaks. Mostly there are also two black dots edged with yellow. A series of black submarginal striae. 30—33 mm. Loja (Ecuador).

3. Genus: **Meleaba** Wkr.

The present comprehension of the genus is rather doubtful. Body delicate, palpi short. Antennae of ♂ shortly pectinated. Forewing with a pointed apex, straight costal and distal margins, while in *Aorista* the costal margin is bent at the base and before the apex. Hindwing dentate at the distal margin near the anal angle and with a projecting lobe. Nothing is mentioned about the neurulation, but according to WARREN it differs much from *Aorista*. Type: *theclaria* Wkr.

theclaria. **M. theclaria** Wkr. White. Wings with 3 greyish brown transverse lines, the first double, the second and third formed of short streaks. Forewing besides with a distinct vertical interior greyish brown line. Hindwing with a yellow spot at the inner margin, enclosing a black dot. Inner margin black at the end, edged with yellow. Very similar to *Morph. candidata* which we figure (170 e), separated by the antennae. 37 mm. Amazons.

urania. **M. urania** Dyar (172 e). White. Forewing with black long transverse streaks traversing the whole wing at the base. Median line straight, brown, faded, and another line in the exterior third, both nearing each other at the inner margin. The streaks at the margin shorter, but partly linearly united. Hindwing with an outward bend above the middle of the distal margin, an orange spot below it with 2 or 3 black dots. A brown line from the middle of the costal margin outward almost to the yellow spot, then rectangularly bent round on to the inner margin. Brown median streaks extend to this line. Black lines in the apical area. 20 mm. Mexico.

antithetes. **M. antithetes** Dyar (172 a). Forewing ochreous, densely dusted with brown, with 2 broad white lines and a discal spot. The interior line obliquely from $\frac{1}{4}$ costal margin to the middle of the inner margin, slightly widened in the middle, excurved below it. The exterior line from $\frac{3}{4}$ costal margin to the anal angle, slightly bent inward at the end. The spot at the cross-vein small and narrow. A pale submarginal shadow from the costal margin to the centre of the wing. Hindwing also with an outward bend, the orange spot below it with 2 black dots. The rest of the hindwing white, the brown streaks showing through from beneath. A fine brown

rectangularly bent median line. Besides a faded brown submarginal and marginal line. 20 mm. Mexico. — The hindwing in both species thus does not quite agree with that of the typical species.

M. comprimaria Geyer (172 g) may be wrongly placed here. Body and wings brownish ochreous. Forewing broadly yellowish brown at the costal margin. Both wings with two double black submarginal undulate lines which are filled with white on the hindwing. The latter is angled above vein 6. 28 mm. South America. *comprimaria*.

4. Genus: **Nedusia** Hbn.

Antennae of ♂ short and stout, laterally flattened, palpi short. Forewing broad, apex pointed. Vein 2 far basad, 3 and 4 from the lower cell-angle, 5 from the upper angle, 6 + 7 stalked, 8 + 9 on a long stalk. Hindwing with an obtuse tail between veins 3 and 4. Veins 3 + 4 stalked, 5 above the middle of the cross-vein, 6 and 7 from the upper cell-angle. Type: *mutilaria* Hbn.

N. mutilaria Hbn. (170 a). Forewing greyish brown with a violet reflection. Interior line only marked by a black dot below the costal margin. Exterior line of dark brown dots, angled at veins 6 and 4, then indistinct as far as vein 2 and from there somewhat outward to the inner margin. Hindwing with a double exterior line from $\frac{3}{5}$ costal margin obliquely outward, projecting far at vein 4, then inward again and continued parallel with the distal margin. A black spot at the little tail. 26—30 mm. Venezuela, Guiana; the specimen figured originates from the surroundings of Blumenau in Sa. Catharina. — **cuticulata** Gn. (173 b) is hardly a different species. Ground-colour dingy white, the lines still more indistinct than in the typical form. Venezuela, Surinam. — *obliteraria* Wkr., according to the kind information of the British Museum, is the same as *cuticulata*. *mutilaria*.

N. castra Jones (172 g) is surely not correctly placed here by the author, perhaps allied to *Lophopygia castra*. *griseata* Warr. (172 h). Body and forewing brown, striated dark brown. Interior line dark, outward to the lower cell-angle, vertical as far as the submedian fold, then inward, somewhat white before it in the cell. Exterior line straight in the figure, according to the description excurved from veins 8 to 2, then downward to the inner margin. Marginal area lighter from the costal margin to vein 4. Hindwing of the same colouring. Interior and exterior lines parallel, dark, rectangularly broken in the middle. 28 mm. Brazil.

5. Genus: **Psamathia** Wkr.

Antennae of ♂ pectinated. The scheme of markings quite similar to that of *Nedusia*, the neuration is also hardly different, except veins 6 + 7 of the hindwing being also stalked. Type: *laticaudata* Wkr.

Ps. laticaudata Wkr. Dark reddish yellow with brown transverse striae. Lines brown. The interior one straight, more distinct on the hindwing than on the forewing. The median line is also straight, vertical, on the hindwing it extends only to the middle. Forewing with another exterior straight line, nearing the median one at the inner margin. A black subapical spot behind it. Hindwing with a pale marginal line which is edged with black in front. Two blackish spots in the tail. 20 mm. Venezuela. *laticaudata*.

Ps. impunctata Warr. is very similar to *laticaudata*, but larger. Forewing without the black subapical spot behind the exterior line. ♂ 46—52 mm. Peru. *impunctata*.

Ps. parallelaria Warr. (170 a). Wings greyish yellow, striated dark. Costal margin of forewing paler. Interior line dark brown, straight, from $\frac{1}{4}$ costal margin to $\frac{1}{3}$ inner margin. Exterior line from $\frac{3}{5}$ costal margin to $\frac{2}{3}$ inner margin, slightly bent. Traces of a submarginal spot between veins 6 and 7 as in *laticaudata*. Hindwing only with an exterior line, shortly and pointedly angled at vein 4. Two black spots on the tail. The ♀ with a still straighter exterior line. The apex of the hindwing projects somewhat more. 25 mm. Costa Rica. *parallelaria*.

Ps. sordidata Schs. Wings grey, finely striated brown. Interior line of forewing fine, dark brown, turned outward. Exterior line strong, indistinctly edged outside with a lighter brown, slightly angled below vein 6. Submarginal spot also present. Exterior line of hindwing strongly angled at vein 4, divided by a lighter brown line. Paler behind it, whitish grey outside, except between veins 3 and 4, two black spots on the little tail. Similar but larger than *parallelaria* (170 a), the exterior line not straight. 29 mm. Costa Rica. *sordidata*.

Ps. placidaria Wkr. (170 b). Wings reddish yellow, finely striated brown. Lines blackish. Interior line of forewing fine, vertical. Exterior line very deeply undulated, composed of spots. Interior line of hindwing oblique, dentate, hardly recognizable. Exterior line double, sharply angled at vein 4, then more indistinct, parallel to the distal margin. — A few specimens from the Chiriqui exhibit a dark shadow behind the exterior line of the forewing above the inner margin. The light filling of the exterior line on the hindwing is very prominent, it is indistinctly edged with dark outside. These specimens are larger, they may be named: — **fuscumarginata** form. nov. 26—32 mm. Venezuela, Chiriqui, Brazil. *placidaria*.

ochriplaga.

Ps. ochriplaga Dgn. (170 a) differs a little in the scheme of markings. Wings greyish brown, the lines blackish brown. Forewing with 2 distinct thick lines. Interior line very obliquely outward, the exterior one less oblique, from $\frac{2}{3}$ costal margin to $\frac{4}{5}$ inner margin. The whole wing striated dark. Near the margin a kind of submarginal line is formed by denser streaks. Hindwing striated only at the distal margin. Interior line fine, almost parallel with the interior margin, indistinct, dentate, connected with the exterior line at vein 4, the exterior line double, almost parallel with the interior one. Ochreous at the little tail as far as the exterior line, 3 bluish black marginal spots between veins 3 and 4. 33—36 mm. Colombia, Costa Rica (Chiriqui).

The following species exhibit the distal margin of the forewing angled at vein 4, slightly cut out above it.

subangulata.

Ps. subangulata Warr. (170 a). Similar to *placidaria* (170 b), but separated by the distal margin. Wings lilac grey, densely striated dark brown, especially at the distal margin of the forewing. Interior line from $\frac{1}{3}$ costal margin to $\frac{1}{3}$ inner margin, with a black spot at the costal margin, then very finely continued. Exterior line very oblique from $\frac{2}{3}$ costal margin, slightly undulated as far as vein 4, then strongly inward and vertically to $\frac{2}{3}$ inner margin. The usual submarginal spot is present. Hindwing with a very dentate exterior line, dark brown and double from the costal margin to the angle, then fine and indistinct. A broad brown shadow at the margin from the apex to the dental projection, and a large spot in the tail. ♂ 30 mm. St. Vincent.

amplata.

Ps. amplata Warr. (170 b). The indentation at the margin is stronger in the ♀ than in the ♂. Similar to *subangulata* (170 a), but larger, the interior line is only discernible at the costal margin. The exterior line shows another slight outward bend in the submedian fold. Hindwing with 3 black lunae behind the exterior line near the inner margin; these lunae are more distinct in the ♀. 34 mm. Paraguay, Rio Grande do Sul. Very dark, indistinctly marked specimens from the Chiriqui in Costa Rica.

6. Genus: **Tricolpia** Warr.

Forewing broad, costal margin bent, apex pointed, distal margin with an angle at vein 4, cut out above it. Vein 3 a little before the lower cell-angle, 5 near the upper angle, 6 + 7 and 8 + 9 + 10 stalked. Hindwing pointedly projecting at vein 4, fine dents at veins 2 and 3, the margin otherwise straight. Veins 3, 4 and 6, 7 from the cell-angles. Antennae of ♂ only laminated, not pectinated. Type: *acutaria* Wkr.

acutaria.

T. acutaria Wkr. (= *biangulata* Fldr.) (170 b). Wings yellowish white. Interior line of forewing dark, indistinct, very obliquely outward as far as the middle of the cell, then vertical to $\frac{1}{3}$ inner margin. Exterior line obliquely outward as far as vein 5, somewhat inward at vein 4, then slightly outward to $\frac{4}{5}$ inner margin. A violettish brown spot behind it below vein 4. Hindwing with double interior and exterior lines, distinct, dark, filled with white, very far extra-angular in the middle. Narrowly brownish at the margin. ♀ darker brown. 20 mm. Venezuela, Guiana, Amazonas.

flava.

T. flava sp. n. (170 b). ♀ distal margin of forewing uniformly bent. Ground-colour reddish yellow, finely striated brown. Exterior line fine, brown, obliquely outward from $\frac{3}{4}$ costal margin to vein 4, slightly extra-angular at vein 6, slightly bent inward below vein 4. Hindwing whitish at the costal margin in the interior part. Exterior line fine, rusty brown, straight, from $\frac{2}{3}$ costal margin to vein 4, where it is angled, and straight to the inner margin shortly before the anal angle. ♀ 20 mm. Goyaz, type in the Senckenberg Museum, taken by Dr. SEITZ in Viannopolis (Tavarez) in February 1930.

7. Genus: **Skaphion** gen. nov.

Palpi short, antennae of ♂ thick. Costal margin of forewing bent before the apex. Apex pointed, distal margin projecting at veins 3 to 4, slightly concave above it. Veins 3 and 4 from the same base, 2 far back, 5 close below the upper cell-angle, 6 + 7 stalked and 8 + 9 + 10 stalked. Hindwing with a point at vein 7, with a broader lobe at vein 3 to 4 than on the forewing, an angle at vein 2, slightly excavated before and behind it. Veins 3 and 4 from the same base, 5 a little above the middle of the cross-vein, 6 + 7 on a short stalk. Type: *lilacina* sp. n.

lilacina.

S. lilacina sp. n. (170 b). Slightly similar to *Trot. metachromata* (170 c). Lilac grey. Interior line of forewing outward from $\frac{1}{4}$ costal margin, angled at the anterior and posterior cell-margins, vertical between, dark, then white, bent inward almost as far as the base at the inner margin. Exterior line white, edged with brown inside, outward as far as the bifurcation of veins 6 + 7, then to vein 4, along which it extends somewhat inward, then to $\frac{4}{5}$ inner margin, concave between. A rusty brown blotch between veins 4 and 6 before the excision, somewhat rusty brown also at the anal angle. Hindwing with both lines white, projecting very pointedly at vein 4, the interior one somewhat indistinct. The exterior one pale brown inside in the anterior part, edged with blackish in the lower part. Broadly bluish white behind it from vein 4 to the inner margin. The veins on both wings lighter. ♂ 18—19 mm. Venezuela, Brazil. Type in the Berlin Museum.

plagifasciata.

S. plagifasciata sp. n. (172 a). Reddish brown. Subcostal vein of forewing lighter brown. The two lines proceed from two large triangular spots, close together. Interior line of black spots straightly inward to $\frac{1}{3}$ inner margin. The exterior row slightly angled outward at veins and below vein 4, then vertical, to $\frac{3}{4}$ inner

margin. On the hindwing the two rows of spots proceed from $\frac{1}{3}$ and $\frac{2}{3}$ costal margin. The interior one is rectangularly angled at vein 2, the exterior one below vein 4. ♂ 13 mm. Itaituba. Type in the Berlin Museum.

8. Genus: **Hypophysaria** *gen. nov.*

Palpi, antennae, forewing as in the preceding genus. Hindwing uniformly bent at the margin between vein 4 and the inner margin, slightly pressed inward between veins 7 and 8, veins 6 and 7 from the same base, the rest as in the preceding genus.

H. integrata Gn. (170 c). Lilac brown. Interior line of forewing dark brown, from $\frac{1}{3}$ costal margin obliquely outward as far as the centre of the cell, then indistinct, vertical. Exterior line outward from $\frac{2}{3}$ costal margin to vein 4, where it forms a small dent, then to $\frac{4}{5}$ inner margin. The line is double, dark brown, filled with whitish. Black at the margin from veins 7 to 4. The brown interior line on the hindwing is rectangularly angled, the exterior line more acutely, double as on the forewing. Blue marginal spots from veins 2—7, edged with black inside. ♀ 22 mm. Brazil.

9. Genus: **Trotorhombia** Warr.

Distinguished from *Nedusia* by the ♂ antennae showing one row of pectinations. Distal margin of hindwing more dentate near the anal angle.

Tr. metachromata Wkr. (= *bisinuata* Fldr., *excavata* Mschlr.) (170 c). Dark violettish grey or violettish brown. The lines blackish brown. Interior line at the costal margin from a black spot, straight, slightly outward, fine. Exterior line angled at vein 4, a little also at vein 6, concave between 4 and the inner margin. The exterior line of the hindwing is double, filled with light, with white spots at the veins. The interior broken line is rather indistinct. *bisinuata* Fldr. and *excavata* Mschlr. (170 c) are the same species. 22—26 mm. Honduras, Portorico, Venezuela, Brazil.

10. Genus: **Coelura** Warr.

Half a dozen rather small, mostly earth-coloured grey lepidoptera with a small excision at the anal angle of the hindwing, distributed from Central America to Southern Brazil and Paraguay. — Proboscis and palpi short. Antennae of ♂ with one row of pectinations. Forewing bent at the costal margin, apex pointedly produced. Vein 5 from the upper cell-angle, 6 + 7 and 8 + 9 stalked. Hindwing with a round apex, a small excision at the anal angle. Veins 3 and 4 from the lower cell-angle or stalked. The genus is purely American. Type: *transversata* Warr.

C. dissocia Warr. (170 c). Greyish brown with fine dark striae, especially at the margin. A blackish brown line from the apex to $\frac{4}{5}$ inner margin. This line is met by another line at vein 5, proceeding from $\frac{2}{3}$ costal margin. Cross-vein faded, dark. A very indistinct strongly bent line at the base. Hindwing with a distinct double exterior line, absent at the lighter costal margin, slightly bent below it. Dark scales above the anal angle. 26 mm. Peru, Chiriqui.

C. omana Drc. (172 a) resembles *dissocia* in its colouring. According to the description it has also the line from the apex and from the costal margin. But judging from the figure the line from the costal margin passes over at vein 5 into the apical line, which begins only there, while a faded line proceeds from the apex, ending a little outside the angle at vein 5. Hindwing with a faded interior band of dark scales and with a dark single median line, more intensely striated dark behind it. 24 mm. Mexico, Central America.

C. strigitermen Dgn. Forewing with a less pointed apex. Wings pale reddish grey. Forewing with a red exterior line from $\frac{3}{4}$ inner margin, extending towards the apex as far as vein 5 and continued from vein 6 inward to $\frac{3}{5}$ costal margin. Dark streaks behind this line as far as the distal margin, blacker at the apex. Hindwing with regular brown streaks, feeble at the base, denser at the margin, blackish. 20 mm. Panama.

C. purpurea Dgn. Forewing with a very pointed apex. Ground-colour lilac brown, the lines and part of the veins blackish brown. Interior and exterior lines fine, distinct, oblique, both introangular towards the costal margin, parallel to each other and to the distal margin. Striated lilac white at the margin, a black shadowy line before it. Hindwing with a strong indentation at the anal angle. Coloured like the forewing, paler at the costal margin. With a median and exterior dark transverse line, straight and parallel. Marginal area as on forewing. 30 mm. Colombia.

C. transversata Warr. (170 c). Apex and anal angle less conspicuous. Forewing reddish yellow, greyer at the costal margin. Lines fine and pale. The first from $\frac{1}{4}$ costal margin, angled below it, then oblique, bent, inside of it faded dark grey. The second line from $\frac{2}{3}$ costal margin, obtusely angled at vein 4, convex above, concave below, edged with a darker colour on both sides. Median shadow and submarginal shadow faded, dark grey. Hindwing paler, straw-coloured at the costal margin. Median shadow greyish brown, blackish before the distal margin. Interior line indistinct, bent, the exterior line angled. 26 mm. Rio de Janeiro.

11. Genus: **Bicavernosa** *gen. nov.*

Antennae thick, palpi short. Forewing with a bent costal margin, apex pointed, distal margin projecting between veins 3 and 4, cut out above it, inwardly bent below vein 3 to the anal angle, veins 3 and 4 separated, 5 below the upper cell-angle, 6 + 7 and 8 + 9 + 10 stalked. Hindwing cut out between veins 7 and 4, feeble angles at 3 and 2. Veins 3 and 4 from the same base, 5 from the middle of the cross-vein, 6 + 7 on a long stalk.

albilunata. **B. albilunata** *sp. n.* (172 a). Forewing greyish brown. A few dark brown transverse lines from near the base to the middle. A brown shadow in the marginal area, bordered inside by a line from the apex to $\frac{2}{3}$ inner margin, where it is steeper. Four bluish white spots in blackish surroundings at the margin before the excision. Hindwing greyish brown at the base. At the cross-vein a thick white luna from which a dark brown line extends to $\frac{1}{3}$ inner margin. Violetish grey behind it as far as vein 5, dark brown above it. Exterior line dark brown, bent from $\frac{2}{3}$ costal margin to $\frac{3}{4}$ inner margin. A few bluish white spots at the excision below vein 7. ♂ 19 mm. Brazil. Type in the Berlin Museum. — *Epiplema albiocellata* Warr., which is no genuine *Epiplema* judging from the neurulation of the forewing, must be very similar, but the neurulation of the hindwing is different.

12. Genus: **Coeluromima** Warr.

Exterior quite similar to that of *Coelura*, separated only by the antennae which show one row of pectinations in both sexes in *Coelura*. Here they are plain in the ♀, with two rows of pectinations in the ♂. Type: *subfasciata* Warr.

reticularia. **C. reticularia** *Mschlr.* (172 a). Judging from the remainders of the wings in the type, the species belongs to this place here. Apex of forewing more pointed than in *subfasciata* (170 c). Forewing reddish brown with a violet reflection. Lines light. Interior line from $\frac{1}{4}$ costal margin to the base of vein 2, where it is angled, and to $\frac{1}{4}$ inner margin. A blackish shadow with bluish white streaks around the cross-vein. Exterior line excurved from $\frac{3}{5}$ costal margin to vein 5, from where it is slightly concave as far as $\frac{2}{3}$ inner margin. A conspicuous white spot in the middle of the marginal area between veins 3 and 4, bluish white striation near the margin. Hindwing dark yellow. Traces of a light interior line. Exterior line bent from below $\frac{3}{5}$ costal margin to the middle of the inner margin, edged dark inside. Blackish behind it from the inner margin to vein 3. ♂ 26 mm. Porto Rico.

subfasciata. **C. subfasciata** Warr. (170 c). Greyish ochreous. Forewing with two dark brown oblique lines from $\frac{1}{4}$ and $\frac{2}{3}$ inner margin, both edged lighter on the averted sides. The first extending to the faded cellular spot, where it is angled and indistinctly inward to the costal margin. The second angled shortly before the apex, then inward, lead-coloured behind it. Hindwing with an indistinct interior line and a better dark exterior line, the latter fadedly edged with dark outside. Blackish streaks at the anal angle. 25 mm. Ecuador.

13. Genus: **Coelurotricha** Warr.

Likewise similar to the *Coelura*-species, but the ♂ hindwing above exhibits a stripe of coarse scales on half the length of the costal margin, and a hair-pencil proceeding from the base. Type: *curvilinea* Warr.

curvilinea. **C. curvilinea** Warr. Wings bone-coloured yellow. Forewing with grey streaks especially at the costal margin. A large round grey spot at the cross-vein. Exterior line fine, bent, from $\frac{2}{3}$ costal margin, obliquely inward to $\frac{2}{3}$ inner margin. It is touched by a round pale yellow, dark-edged spot. A submarginal stripe of grey streaks, edged with yellow. A small dark spot above vein 6. Hindwing with an exterior line from veins 6 to 2. Intensely striated grey behind it, except at the apex. Hair-pencil at the costal margin dark greyish brown. 24 mm. Panama.

imitans. **C. imitans** *Dgn.* Similar to *Coelura transversata* Warr. (170 c). Greyish ochreous, with lilac scales in the marginal area. Forewing with 2 brown transverse lines, edged with ochre outside. Interior line slightly bent. Exterior line bent inward from the inner margin to vein 5, where it is angled and slightly excurved to the costal margin at $\frac{2}{3}$. A faded black shadow at the cross-vein. A triangular submarginal spot above vein 6. Hindwing with 2 similar lines. An interior line composed of two dots. Exterior line hardly incurved from the inner margin to vein 5, where it is angled, and ending at vein 6. 28—30 mm. Colombia.

14. Genus: **Morphomima** Warr.

Forewing with a slightly produced apex, distal margin excurved in the middle. Veins 2 and 3 on a short stalk, 4 from the angle, 5 close below the upper cell-angle, 6 + 7 from the angle, 8 + 9 + 10 stalked. Hindwing with a broad apex, the margin straight as far as vein 4, somewhat dentate at 2, 3 and 4, cut out below vein 2. Vein 2 shortly before the lower cell-angle, 3 and 4 from the angle, 5 near the upper cell-angle, 6 and 7 separated. Antennae of ♂ thick, shortly dentate, palpi somewhat longer than usual. Veins 2, 3 and 4 of ♀ forewing separated. Veins 6 and 7 of hindwing from the cell-angle or on a short stalk. Type: *opigena* Drc.

opigena. **M. opigena** *Drc.* (= *fulvitacta* Warr.) (170 d). Ground-colour white. Forewing of ♂ in typical specimens brownish in the basal half. Interior line dark, double, from the middle of the costal margin to the inner margin.

near the base. Exterior line also double, from near the apex to $\frac{2}{3}$ inner margin, distal margin brown, rusty yellow at the apex. Hindwing white at the costal margin. Interior line brown, slightly bent, darker before it. Exterior line double, bent. Marginal area more intensely dark, with a light median band. A ♀ from Bolivia is very large, dusted much darker. On the other hand there are also specimens showing hardly any brown dusting at all. 25—30 mm. Nicaragua, Colombia, Bolivia.

The following species were formerly ranged under the genus *Syngria*, but as their neuration is different, I place them here. The antennae of the ♂ seem to be somewhat longer pectinated, the scheme of marking in *acalis* is very similar to that of *Syn. druidaria* (170 f), the other species are differently marked.

M. acalis *Fldr.* (170 d) is rather variable. Wings creamy white. Forewing narrowly violettish brown at *acalis*. the costal margin, the basal half as far as the cross-vein also violettish brown, mostly less prominent below vein 2. Sometimes a yellowish interior line in it, recognizable as in *druidaria* (170 f). Exterior line yellow, edged with brown inside, from the costal margin straightly outward to vein 4, where it is sharply angled, and curved to the inner margin. A subapical black dot. Brown at the margin especially in the lower part. Hindwing with an exterior line between veins 6 and 2 as in *druidaria*, sharply angled at vein 4, whitish, edged with brown inside. Rusty brown above the lowest small tail, adjoining to it a submarginal band of brown scales. One part or another of the marking may be absent, rarely everything is present. 26—30 mm. Central America, Colombia. — **griseata** *Warr.* (170 d) is probably only a very dark specimen in which the dark dusting on the *griseata*. forewing extends to the extinct exterior line, while the light exterior line on the hindwing is not prominent in spite of the intense darkening. 34 mm. Peru.

M. versilinea *Dgn.* is probably a separate species. Ground-colour greyish white with dark streaks, *versilinea*. especially at the costal margin of the forewing. The two lines white, edged with brown at the costal margin, the interior line bent, the exterior one as in *acalis* (170 d). Beside the black subapical spot there are yet black streaks in the marginal area. Costal margin of hindwing white, the rest like the forewing. The exterior line projects pointedly at vein 4. 32—36 mm. Ecuador, Colombia.

M. candidata *Warr.* (170 e) is very different. Ground-colour white. Forewing with a dark brown marking. *candidata*. A double streak at the cross-vein down to vein 2. Exterior line slightly outward at the costal margin, then vertical, double as far as vein 4, where it is very fine, prolonged towards the base, then distinct again, vertical double, to $\frac{3}{4}$ inner margin. Submarginal line interrupted. Exterior line of hindwing double, somewhat angular in the middle, not reaching the costal and inner margins. Submarginal line traceable, a black spot above and below it near the anal angle. 30 mm. Peru.

M. albipennaria *H.-Schäff.* (170 e) is somewhat similar to *candidata*. Wings white with light olive brown *albipennaria*. transverse lines. Forewing with an interior line from $\frac{1}{4}$ costal margin to $\frac{1}{3}$ inner margin. Median line double, straight, slightly oblique. Exterior and submarginal lines composed of dense striae, parallel with the median line. Hindwing with a double median line. The two other lines only formed of striae meeting at an intense spot above the anal angle. The anal angle itself rusty yellow. 30—35 mm. Venezuela, Colombia, Bolivia, Brazil.

? **M. cinerea** *Warr.* (170 d). Dark grey, dusted black. Forewing with traces of 3 faded black bands at *cinerea*. the base, before the middle and at $\frac{2}{3}$ of the length of the wing, the last somewhat more distinct, extra-angular in the middle, below it curved inward. Veins in the marginal area paler. Hindwing with black scales at the base. Traces of a median and submarginal shadowy band. Paler grey at the inner margin. Veins yellowish ochreous. Black dots near the anal angle. 24 mm. Venezuela.

ramosaria *Mschlr.* placed to this genus by DALLA TORRE belongs to the *Geometridae*.

15. Genus: **Schidax** *Hbn.*

Forewing pointed at the apex, slightly cut out below it, excurved at the middle of the distal margin. Veins 3 and 4 near the lower cell-angle, 5 a little below the upper one, 6 + 7 on a short stalk, 8 + 9 on a longer stalk. Hindwing with 2 bows near the anal angle and a rounded margin. Antennae of ♂ and ♀ pectinate. Type: *squammularia* *Hbn.*

S. squammularia *Hbn.* (170 e). Wings greyish white, striated dark. Anal angle of forewing and exterior *squammularia*. half of hindwing brown, rarely with a brown median band as HÜBNER figures the species. Interior line of forewing from $\frac{1}{3}$ of costal margin fine, black, dentate, very obliquely inward. Exterior line projecting in the middle of the wing, very strongly notched. 25—30 mm. Nicaragua, Cayenne, Brazil.

S. anosectaria *Gn.* (170 e). Wings greyish brown with dark striae. Forewing often somewhat darker *anosectaria*. at the cross-vein and anal angle. Exterior line of forewing dark brown, shaped as in *squammularia*, no interior line discernible. 28—30 mm. Brazil. *Erosia similaria* *Wkr.* is probably the same species.

S. evulsa *Fldr.* (170 f). Similar to a large *anosectaria*. Reddish brown. Interior and exterior lines of *evulsa*. forewing fine, distinct, black. Interior line excurved in the middle, exterior line finely notched, straight as far as vein 3, incurved between veins 3 and 1. A black streak before the exterior line at the costal margin. A dentate marginal line parallel with the margin. Hindwing greyish brown, with the light spots at the anal angle as in the two preceding species, but larger, the distal margin more excurved. 40 mm. Guiana.

coronaria. **S. coronaria** *Strecker* (170 e) has the wing-contours of *evulsa* (170 f), but it is smaller. Wings grey, glossy. Forewing with traces of an exterior strongly notched line from the costal margin to vein 5. A few dark spots outside at the costal margin. 30 mm. Florida.

canoferata. **S. canoferata** *Wkr.* Grey, indistinctly striated, rusty brown at the distal margin. Exterior line black, strongly notched, somewhat interrupted on the forewing, with a black radial streak at the base. Interior line black, notched. A few black spots at the costal margin. Hindwing with a notched black median line. Brown between it and the exterior line. 34 mm. Ega.

serraria. **S. serraria** *Wkr.* and *canoferata* may be identical with the variable *squamularia* (170 e). Reddish yellowish grey, striated dark. Exterior line as in *canoferata*. Somewhat reddish yellow at the distal margin. 35 mm. Rio de Janeiro.

Each of the following species has different contours of the wings.

saginata. **S. saginata** *Gn.* (172 a). Light violettish brown, striated dark. The marking consists only of an exterior row of indistinct black dots and a few marginal dots in the anterior part. Hindwing with a red-brown line before the exterior row of dots and two short bands of dark scales extending from the cell to the inner margin. ♀ 28 mm. Cayenne. It is doubtful whether the species belongs to this place, it is very similar to *Molybdophora concinnaria* *Hbn.* (172 g).

fuligaria. **S. fuligaria** *Gn.* (170 f). Distal margin of forewing slightly projecting at vein 6. Veins 3 and 4 close together, bent somewhat upward at their origin. Veins 6 + 7 of hindwing on a very long stalk. Wings dark violettish grey, with a lead-coloured submarginal line, fringe rusty brown. Forewing with a rusty brown ray from the base almost to the margin below vein 5, then upward before the lead-coloured line. Hindwing with traces of a rusty brown submarginal line and black dots at it in the posterior part. 20 mm. Guiana.

semissaria. ? **S. semissaria** *H.-Schäff.* (172 b). Wings light greyish yellow, striated darker. Both wings with interior and exterior lines, dark brown, parallel, strongly angled in the middle, somewhat undulated. Forewing with a dark apical streak and a line from the base of the wing to the centre of the margin. 24 mm. Surinam. HERRICH-SCHÄFFER's figure which is copied here may be a bad figure of *acutaria* *Wkr.* (170 b).

repandaria. ? **S. repandaria** *Wkr.* Greyish brown, with 3 indistinct brown transverse lines. The first two undulated, the third notched. Distal margin angled in the middle. 35 mm. Bogota.

16. Genus: **Syngria** *Gn.*

This genus was formerly quite differently comprehended. To-day it is confined to one of the largest and commonest species of the *Epiplemidæ*. — Antennae short, laterally compressed. Palpi thin, long. Abdomen of ♂ with a long anal tuft. Forewing with a very pointed apex, a sharp anal angle, the margin in the ♂ slightly excurved at vein 6. Vein 2 a little before the angle, 3 and 4 from the lower cell-angle, 5 close at the upper angle, 6 + 7 on a long stalk, 8 + 9 on a very long stalk. Hindwing of ♂ with points at veins 2, 3 and 4, the anal angle cut out below 2. Veins 3 + 4 stalked from the lower cell-angle, 5 above the middle of the cross-vein, 6 from the upper angle. 8 and 7 swollen at the base, 7 branching off from the centre of the cell. ♀ only with a point at vein 3, the anal angle is also cut out. Veins 3 and 4 as well as 6 and 7 from the cell-angles or on very short stalks. Type: *druidaria* *Gn.*

druidaria. **S. druidaria** *Gn.* (♀ = *falcinaria* *Gn.*) (170 f). The species varies extraordinarily much in its colouring and the distinctness of the marking. The very conspicuous light spot on the forewing may also be quite absent above and almost entirely absent beneath. Ground-colour light yellow, greyish yellow, red-brown, dark violettish brown. — Sometimes also the median area is of a much lighter colour than the rest. Such specimens are called: **derwaria** *Oberth.* (172 g). Interior line of forewing vertical, straight, only at the costal margin slightly inward. Exterior line more angled at vein 4, less so at the partition of 6 + 7, bent inward between vein 4 and the inner margin. On the hindwing the interior line joins that of the forewing. Exterior line from the middle of the costal margin obliquely outward to vein 4, where it forms a very pointed angle, and a feebler one below vein 2. The little tails are black. Forewing mostly with a black subapical dot. A light submarginal spot between veins 2 and 4, also beneath. 35—50 mm. — From Mexico to Brazil, apparently very common. — *drepanata* *Fldr.* only known as a ♀ is surely only based upon large specimens of *druidaria*; before me there is such a specimen from Venezuela, at least as large as FELDER's figure of it.

17. Genus: **Syngriodes** *Warr.*

The genus is not described by WARREN, but owing to the statement that *incisaria* *Wkr.* belongs to it, it is characterized. Forewing of ♀ with a pointed apex and angle at vein 4. Veins 3 and 4 close at the lower cell-angle, 2 a little back. 5 near the upper cell-angle, 6 + 7 stalked on half their length, 8 + 9 stalked. On the hindwing veins 3 + 4 and 6 + 7 are stalked, 5 from the middle of the cross-vein. Hindwing of ♂ (in

incisaria) with a brown hair-pencil at the costal margin above proceeding from the base, at the anal angle without dents. Type: *incisaria* Wkr.

S. discolor Warr. (170 g). ♀ yellowish white. Forewing somewhat brownish at the base. The lines *discolor*. pale, edged dark. Interior line strongly bent inward at $\frac{1}{5}$ of the length of the wing. The exterior one bent below the costal margin, then straight and obliquely inward to $\frac{2}{3}$ inner margin. Traces of a dark median line and a spot at the cross-vein. Somewhat dark before the middle of the distal margin. Hindwing with a curved exterior line. An ochreous hue before it in the middle. ♀ 28 mm. Costa Rica.

S. incisaria Wkr. (170 g). Yellowish white, dusted with brown of a variable intensity. Interior line *incisaria*. of forewing finely brown, extending as in *discolor*. A fine white dot at the cross-vein, a large brown spot behind it. Exterior line also like that of *discolor*, mostly only the interior dark edge is somewhat distinct. The brown submarginal shadow is continuous. Hindwing with a dark exterior and submarginal band of brown scales. 22—30 mm. From Mexico to Brazil.

S. acinacidaria H.-Schäff. (172 b) presumably belongs to this place. ♀ similar to *incisaria*. Whitish, *acinacidaria*. densely striated pale brown. Forewing with a luniform spot at the cross-vein, with incurved points, a dark line extending from it to $\frac{1}{3}$ inner margin. Exterior line feebly double, incurved towards the costal margin, where it shows black spots which are absent in *incisaria*. The subapical spot and the dark striation before the margin as in *incisaria*. Hindwing striated the same as in *incisaria*. An interior and exterior line traceable in the original figure. ♀ 28 mm. Venezuela.

S. genaria sp. n. (= *opigena* ♀ *Drc.*) (170 g) resembles *incisaria*. Yellowish. Forewing somewhat *genaria*. brownish in the interior half. A white spot at the cross-vein, with an indistinct brown spot outside. The interior line extends from the white dot straightly inward to $\frac{1}{4}$ inner margin, brown outside, yellowish white inside; towards the costal margin it extends indistinctly, notched, inward. Exterior line brown, white outside, from $\frac{2}{3}$ inner margin, outward below vein 1, obliquely upward as far as vein 5, then quite indistinct. A rusty brown submarginal shadow in the anterior half. Hindwing with traces of a broad median and submarginal band of rusty brown dusting, extending from the inner margin to the centre of the wing. 26—30 mm. Central America, Brazil. The ♂ probably belonging to it has very hazily marked wings, dark bands instead of the lines.

S. cassera Drc. (170 g). Red-brown or dark brown. Forewing with 3 very indistinct dark transverse *cassera*. bands. The interior line vertical on $\frac{1}{4}$ inner margin. The next one before the middle of the inner margin somewhat obliquely outward and a parallel one from $\frac{2}{3}$ inner margin, the two last bent inward at the costal margin. Hindwing with a straight interior line, somewhat extinct. Median line uniformly bent, darker behind it. The apex of the ♀ forewing projects very far. 28—32 mm. Central America.

S. adjectaria Wkr. Similar to *acinacidaria* (172 b). White, dusted greyish brown. Interior line of *adjectaria*. forewing very indistinct. Exterior line white, partly edged with black inside, angled in front. There is no central spot mentioned on the forewing, but there is such a spot on the hindwing. Lines apparently not discernible. The anal angle is very much cut out, the dents beside it feeble. ♀ 22 mm. Venezuela.

S. aeolis Schs. White. Forewing somewhat pale brown at the base, grey at the costal margin. An *aeolis*. exterior row of small spots formed of brown scales. A brown submarginal shadow behind them. Hindwing with an indistinct interior line, the exterior line better visible, spotted. The dark scales are more densely arranged at the anal angle, brown scales are also at the margin. Forewing of ♀ with an interior line of more densely arranged scales, a median band is also traceable. A small marginal spot above vein 4, dark scales above the anal angle. 20 mm. Costa Rica.

18. Genus: **Hyperplema** Warr.

Proboscis small, palpi long, antennae of ♂ bipectinated. Forewing oblong, apex obtusely rounded, distal margin without angles. Veins 2, 3 and 4 at equal distances, 5 below the upper cell-angle, 6 + 7 and 8 + 9 + 10 stalked. Hindwing narrow, with an indentation at the anal angle. Vein 5 above the middle of the cross-vein, 6 + 7 on a short stalk. ♂ forewing with a hyaline spot at the base. Type: *rudis* Warr.

H. rudis Warr. (170 g). Greyish brown. Forewing somewhat darker at the costal margin. The two lines *rudis*. dark, angled. The first at $\frac{1}{3}$ of the length of the wing, angled below the costal margin and at the median vein, then obliquely inward. The second line at $\frac{2}{3}$, obliquely outward, sharply angled at vein 7, then undulate, obliquely inward. A fine black dot at the cross-vein. Hindwing with a double dark interior and exterior line. Cellular dot black. ♂ 20 mm. "Onoribo".

19. Genus: **Leuconotha** Warr.

Proboscis absent, palpi long porrect. Antennae of ♂ bipectinated, serrate in the ♀. Forewing with a round costal margin and apex, the distal margin oblique, bent. Veins 3 and 4 close together, 5 below the upper cell-angle, 6 + 7 and 8 + 9 + 10 stalked. Hindwing rounded. Vein 3 well separated from 4, 5 from the middle of the cross-vein, 6 + 7 on a short stalk. Type: *venosa* Warr. The 4 species described are very much alike and do not look like *Eplipemidae* at all.

venosa. **L. venosa** Warr. (170 h) is all white, all the veins dark brown. Costal margin of forewing black at the base. 20–24 mm. Venezuela.

albida. **L. albida** Dgn. Body white, the wings also white, the veins somewhat more coloured. Similar to *venosa* Warr. (170 h), but smaller, whiter, the veins less prominent. 23 mm. Described according to a ♀ from the Rio Tapajoz (Amazons).

subfumida. **L. subfumida** Warr. (170 h). Brownish white. Costal margin of forewing and all the veins brown. Hindwing with but slightly darker veins and a lighter costal margin. ♂ 20 mm. Venezuela.

persordida. **L. persordida** Warr. (170 h). Wings greyish brown, the veins on both wings dark. Forewing with traces of a dark interior and exterior shadow. Hindwing with a more intensely black cross-vein. Forewing beneath with a black subapical dot. ♂ 22 mm. Bolivia.

20. Genus: **Siculodopsis** Warr.

The 6 very similar species which owe their generic name to a purely habitual resemblance to some *Thyrididae* are all American. — Proboscis present, palpi short, antennae of ♂ pectinate, anal tuft long. Forewing of the typical species oblong, costal margin slightly bent, apex somewhat pointed. Vein 3 a little before 4; 5 and 6 + 7 from the same base, 8 + 9 stalked. Hindwing rounded, anal angle insignificantly lobate. Type: *flaviceps* Warr. All the species look insignificant.

flaviceps. **S. flaviceps** Warr. (170 h). Greyish ochreous, finely striated blackish. Forewing with a black subapical dot which is absent on the hindwing. ♂ 28 mm. São Paulo.

pallidifrons. **S. pallidifrons** Warr. (170 h). Similar to a small *flaviceps*. Forewing dingy pale grey, browner at the costal margin. A dark indistinct spot at the cross-vein, a short black streak near the apex, with no other marking. Hindwing somewhat darker grey, dusted brown. A black dot at the cross-vein. ♂ 20 mm. Ecuador.

dubia. **S. dubia** Warr. Dingy pale grey, spotted darker. Costal and distal margins fadedly darker. Cellular spot brown, a dark indistinct band at $\frac{3}{4}$ of the length of the wing. Hindwing also with a cellular spot and traces of a curved grey submarginal line. ♂ 24 mm. Ecuador.

gracilinea. **S. gracilinea** Warr. Pale reddish grey with fine brown striae. The lines indistinct, brown. The first from below $\frac{1}{3}$ costal margin obliquely inward, interrupted. The exterior line from the middle of the costal margin obliquely outward to vein 7, then straight, inward. On the hindwing only the exterior line is recognizable, costal margin paler. ♂ 24 mm. Peru.

grisea. **S. grisea** Warr. (170 h) has broad wings. Dingy grey with black streaks especially at the costal margin. The streaks form an indistinct interior and exterior band. A rather large black subapical spot above vein 6. Also the hindwing with an indistinct interior and exterior shadowy band. ♂ 28 mm. Ecuador.

semifasciata. **S. semifasciata** Dogn. Grey, the spots and marking blackish brown. The interior line of the forewing is marked by a spot at the costal margin and a small one at the median vein at $\frac{1}{3}$ of the length of the wing. The exterior line marked by a blackish shadow at $\frac{2}{3}$ of the length of the wing and by spots at veins 7, 6, 4, 3 and 2. A small black oblique streak at the apex and two marginal spots between veins 7 and 5. Brown streaks on the whole wing, more densely arranged at the costal margin and at $\frac{3}{4}$ inner margin. A white spot at the cell-end, a brown streak before it and the brown cross-vein behind it. Hindwing with a few streaks at the inner margin and the beginning of a submarginal line.

21. Genus: **Hemioplisis** H.-Schäff.

Antennae of ♂ with one row of pectinations. Forewing with a pointed apex, distal margin excurved above the anal angle. Vein 5 far in front, 6 + 7 on a short stalk, 8 + 9 + 10 stalked. Distal margin of hindwing uniformly rounded, apex and anal angle rather sharp. Type: *drepanularia* H.-Schäff.; it differs somewhat from the other species in the scheme of markings.

drepanularia. **H. drepanularia** H.-Schäff. (171 a). Violetish brown. Interior line fine black, extra-angular from $\frac{2}{5}$ costal margin to the cross-vein, then very oblique to $\frac{1}{3}$ inner margin. Exterior line dark brown, from $\frac{2}{3}$ costal margin obliquely outward to vein 6, where it is bent round, straightly towards $\frac{3}{5}$ inner margin, slightly extra-angular at vein 1. A distinct black line from the apex to the angle at vein 6. The median area somewhat lighter. The lighter median area on the hindwing extends almost to the base. Exterior line from $\frac{2}{3}$ costal margin to $\frac{2}{3}$ inner margin, semicircularly excurved behind the cell. ♂ 30 mm. Brazil.

maculata. **H. maculata** Warr. (171 a). ♂ forewing reddish brown, with fine black transverse streaks, paler at the costal margin. Interior line indistinct, from $\frac{1}{3}$ costal margin, angled in the cell, to $\frac{1}{3}$ inner margin. The space before it dark red-brown. Exterior line from the apex uniformly bent to $\frac{3}{5}$ inner margin, edged with white inside. The margin behind it as far as vein 3 upward red-brown. Hindwing red-brown in the basal and marginal areas. Interior line on $\frac{1}{4}$ of its length, exterior line at $\frac{3}{5}$. ♀ dark violetish brown. Interior line more distinct, steeper at the inner margin. Exterior line from $\frac{2}{3}$ costal margin sharply angled at vein 7, otherwise as in the ♂.

The median area is scarcely lighter. Hindwing with but one line from the middle of the inner margin for some distance in front, bent. 29—33 mm. Venezuela.

H. fallax Warr. (171 a) resembles a species of *Decetia*. Wings dull flesh-coloured, dusted darker, costal margin broadly paler. Traces of an interior line at $\frac{1}{4}$, slightly extra-angular in the cell. Exterior line pale, red-brown outside, straightly obliquely inward from the apex to vein 2, then vertical to $\frac{2}{3}$ inner margin, where there are two brown spots close behind it. Hindwing with a short line from the middle of the inner margin. ♂ 26 mm. Venezuela.

The two following genera may belong to the genus *Saccoploca*.

H. metallica Warr. (171 a). Distal margin of forewing much more excurved, distal margin of hindwing straighter, apex rounder. Forewing dark red-brown, finely dusted with greyish blue. The lines very indistinct, dark brown, edged with bluish grey scales. Interior line from $\frac{1}{3}$ costal margin to $\frac{1}{4}$ inner margin, broadly excurved in the middle of the wing. Exterior line from $\frac{3}{5}$ costal margin to $\frac{3}{5}$ inner margin, obliquely outward as far as vein 6, then bent, and straight from vein 4. Distal margin with bluish grey scales below the middle, a white spot above and below vein 3. Hindwing with a double dark brown median line, darker between. Marginal line rusty red, white dots before it. Besides 1 dot above vein 3 farther inward. ♀ 26 mm. Trinidad.

? **H. alternata** Warr. (171 a). Dull violettish grey, darker at the inner and distal margins. Interior line dark, from $\frac{1}{3}$ inner margin straightly towards the apex, but sharply angled at vein 4, bent inward to the costal margin. A bent line from the middle of the inner margin, angled at vein 7 and inward to the costal margin. Submarginal line dark, somewhat undulated, bent inward at the costal margin, darkened before and behind it in the anterior part. Hindwing with a straight double black interior line. Exterior half dusted black, distal margin warming into reddish yellow. Apex of forewing truncate, at vein 7 the margin projects a little, only veins 8 + 9 are stalked. Also the hindwing shows a slight angle at vein 7. This description differs somewhat from the figure. ♀ 18 mm. Peru.

22. Genus: **Falcinodes** Gn.

Antennae of ♂ shortly pectinated, plain in the ♀. Forewing with a projecting apex, distal margin oblique, anal angle rounded. Distal margin of hindwing slightly bent, anal angle rectangular. Type: *corvinaria* Gn.

F. corvinaria Gn. (172 b). Lead-coloured, dusted with violettish brown. Interior line of forewing excurved from $\frac{1}{3}$ costal margin to the cross-vein, where it is obtusely angled, then to $\frac{1}{4}$ inner margin. Exterior line from $\frac{2}{3}$ costal margin bent parallel to the interior line, from vein 2 somewhat outward to the inner margin, edged white in the bend behind the cell, extending more finely to vein 2. Behind the cell a branch of the exterior line runs to the apex. Hindwing lighter at the costal margin. Both the transverse lines fine, parallel, slightly excurved in the middle. ♀ 35 mm. Cayenne.

F. gazzinaria Oberth. (172 b). Forewing coloured like *corvinaria*, only the costal margin broadly brownish ochreous, with somewhat darker clouds. Interior line only in the dark part, light, undulate, somewhat inward to $\frac{1}{3}$ inner margin. Exterior line light, vertical to $\frac{3}{5}$ inner margin, excurved close above the inner margin, edged with red-brown outside as far as the apex. Hindwing lighter, with an indistinct median line, angled in the middle. — **plagataria** Oberth. (173 a) shows a quadrangular yellowish spot down as far as vein 1 between the two lines on the forewing. 38 mm. Guiana.

F. perstrigata Dgn. Wings violettish brown, brownish ochreous at the costal margin. Exterior line brown, edged with ochre inside, beginning at $\frac{2}{3}$ inner margin at a black dot, bent inward between veins 1 and 2, straight as far as vein 5, obliquely outward, ending at vein 7 below the apex, a branch extending from vein 6 inward to the costal margin. Interior line from the costal margin near the base to the inner margin at the base, extra-angular in the middle of the cell. 3 white submarginal dots between veins 2 and 5. Hindwing with 2 lines as a continuation of those on the forewing, extra-angular in the middle. 30—40 mm. Guiana.

F. rufula Warr. (171 b). Shape of wings and scheme of markings different. Ground-colour reddish yellow, the lines indistinct. Interior line from $\frac{1}{4}$ costal margin, strongly excurved in the cell, then inward. Exterior line from $\frac{2}{3}$ costal margin obliquely to the middle of the inner margin and there near the interior line. Striated in lead-colour between the two lines; similar streaks close at the base. Submarginal line marked by a black spot above and below vein 4. Hindwing with somewhat darker median and submarginal bands. ♀ 28 mm. Bolivia.

gonodontaria Sn. and *suggilaria* Sn. seem to be no *Epiplemidæ* according to the author's statement about the neururation.

23. Genus: **Saccoploca** Warr.

This genus is composed of a dozen of species nearly all of which are rather monotonously blackish brown and which exhibit a great resemblance partly to some *Drepanidæ* (for instance from the genus *Psiloreta*) and partly to some *Geometridæ* (such as the genera *Achlora*, *Nereia* etc.). — Palpi short, porrect, antennae of ♂ finely serrate, laminate in the ♀. Forewing broad, triangular. Apex pointed, distal margin of ♀ cut out below it. Vein 5 from the upper cell-angle, with 6 + 7 from the same base, 8 + 9 on a long stalk. Hindwing with

a rounded apex, the anal end angled. Inner margin of ♂ turned over, containing hair-flocks. Hindwing of ♀ normally shaped. Veins 3 + 4 and 6 + 7 stalked. Type: *excisa* Warr.

In the first two species the exterior line of the forewing extends to the apex.

sordida. **S. sordida** Warr. (171 b). Light ochreous, spotted dark, costal margin darker brown. A blackish brown streak before and behind the middle, and adjoining to each of them an indistinct transverse line. From the apex to vein 4 a line obliquely inward, then bent round to the anal angle, black spots between the veins in the lower part of the line. The distal margin behind it browner, the apex before it lighter. Hindwing lighter at the costal margin, the two brown lines beginning below the cell. ♂ 25 mm. Peru.

divergens. **S. divergens** Warr. (171 b). Violettish brown, striated dark red-brown, with a few blue scales. Interior line rusty brown, rather indistinct, far excurved from $\frac{1}{4}$ costal margin, obliquely inward from the median vein to $\frac{2}{5}$ inner margin. Exterior line from $\frac{3}{5}$ inner margin to the apex, bent round close before it, bluish white, edged blackish inside, rusty red outside. Blackish between the two lines above the inner margin. Marginal area lighter. Hindwing with an interior and a median bluish white line, edged with rusty brown on both sides. Marginal area lighter. In this species the forewing of the ♀ is not cut out at the margin. 24–30 mm. Peru, Bolivia.

In the following species the exterior line extends almost parallel to the distal margin.

strigaria. **S. strigaria** Jones (172 c). Light olive brown, dusted violettish brown, costal margin lighter. Interior line dark brown, from $\frac{1}{4}$ costal margin obliquely to the middle of the cell, then vertically to $\frac{2}{5}$ inner margin. Exterior line from $\frac{3}{4}$ costal margin, very slightly excurved at first, then almost straight to the middle of the inner margin. Hindwing broadly light at the costal margin, somewhat darker at the base. Interior and median lines close together, straight. ♂ 26 mm. Brazil.

brunneata. **S. brunneata** Dgn. Light brown. Interior line of forewing dark brown, bent at the costal margin, slightly inward in the submedian fold. Exterior line strong, with faded edges, from the middle of the inner margin to $\frac{4}{5}$ costal margin, where it is slightly bent inward. Behind it a parallel line, dark, white in the middle. This white line is only inwardly edged with dark above vein 4, and both disappear at vein 6. A parallel submarginal line behind it. Hindwing pale at the costal margin. The dark brown median line proceeds from a red-brown spot at the inner margin. ♂ 26 mm. Colombia. The species seems to resemble a large *alternata* Warr. (171 a).

brevimargo. **S. brevimargo** Warr. (= *consimilis* Warr. ♀) (171 b). The inner margin of the hindwing is shorter here and the anal angle thereby rounded, not angled. Violettish brown, dusted dark, the apex of the forewing more yellowish brown. The lines dark brown, distinct. Interior line from $\frac{1}{3}$ costal margin horizontally into the cell, where it is angled and straight to $\frac{1}{3}$ inner margin. Exterior line from $\frac{2}{3}$ costal margin to $\frac{2}{3}$ inner margin, slightly excurved. Five black dots from the apex obliquely inward. On the hindwing both the lines are bent and distinct. The ♀ of it is said to be an insect which is described as *S. consimilis* Warr. ♀ and which is said to have no excision at the distal margin of the forewing. It is not stated whether the inner margin of the hindwing is also shortened in the ♀. 35 mm. Peru.

hendida. **S. hendida** ♀ Dgn. (= *consimilis* ♀ Warr.) (171 b). The ♀ is said to have the lower angle at the distal margin between veins 2 and 3, which is presumably only a mistake instead of 3 and 4. Wings greyish brown in the interior half, greyish red outside, the border-line red, edged with grey, straight; whether it is vertical or oblique is not stated. The anterior part of the forewing is said to be traversed by bluish feeble fine lines, especially in the marginal area, thus very conspicuous, though WARREN does not mention it in the description of his *consimilis* ♂ or ♀. Black submarginal dots around the excision. Hindwing not described. The ♂ is described to resemble *excisa* Warr. (171 c), but smaller, the apex more pointed. Transverse lines on both wings very fine. Hindwing beneath often brownish ochreous at the distal margin. The ground-colour is not mentioned, but according to our figure it is dark violettish brown with a blue reflection, brownish ochreous only in the anterior part of the hindwing. 30–35 mm. Peru. — A specimen before me, collected by FASSL and labelled as *hendida* ♂, shows some resemblance to the *hendida* ♂ figured by us merely in the ground-colour. The distal margin is almost still steeper than it is figured in *divergens*, the exterior line likewise proceeds from $\frac{2}{3}$ inner margin into the apex. The interior line is shaped as in *brevimargo*, thus angled below the costal margin, then straight. On the hindwing an interior and a median dark line are to be noticed, similar to *brevimargo*. Abdomen orange at the end. Without seeing a specimen or figure of the genuine *hendida* ♀, one cannot ascertain whether the ♂ belongs to it or not, and it seems to me to be useless to denominate it. ♂ 26 mm. Lino Panama, 800 m. A figure, however, may be useful, for which reason we add it (171 b).

excisa. **S. excisa** Warr. (171 c). ♂ dark violettish brown, strewn with fine bluish white scales, especially in the marginal area. The lines darker. The interior line from $\frac{1}{4}$ costal margin outward, shortly bent in the cell, somewhat obliquely inward to the inner margin at $\frac{1}{3}$. Exterior line from $\frac{3}{4}$ costal margin to $\frac{2}{3}$ inner margin, slightly excurved, edged with bluish white. A violet submarginal shadow from the apex to vein 4. Hindwing pinkish brown at the costal margin. The two lines extend only through the cell. The ♀, with an excision on the forewing, is browner, the blue scales denser at the margin. — **nigrosticta** Warr. (171 c) is more wood-coloured brown, the lines less distinct. Black submarginal spots before the excision which is deeper than in *excisa* ♀.

The margin intensely dusted with blue. Hindwing with traces of the two transverse lines. According to the figure the forewing is without the interior line, the exterior line seems to be steeper, broadly edged with grey inside. 30—32 mm. Peru.

S. consimilis Warr. (171 c). The right *consimilis*-♀ (thus not the present *brevimargo*-♀) exhibits an *consimilis*. excision at the margin of the forewing. According to the figure the species is somewhat darker than *excisa*-♀. Both wings without the interior line. The exterior line on the hindwing seems to end at the inner margin a little farther outside. 28 mm. Presumably also from Peru. — Considering the variability of some South-American *Epiplemidæ*, it might be possible that *brevimargo*, *hendida* and the “right” *consimilis* are all forms of one species. The correct determination is made almost impossible by the inexact description of *hendida* and the distribution and displacing of the name *consimilis*.

S. delicata Kaye. Described as *Syngria*. Body and wings pale brownish pink. A whitish spot with a *delicata*. black marginal line inside is at the cross-vein of the forewing. The two lines are olive brown. The interior one projects pointedly to the discal spot, from where it extends very obliquely inward to the costal and inner margins, rather indistinct. Exterior line from the costal margin almost horizontally outward as far as vein 7, where it is angled and straight to $\frac{3}{5}$ inner margin, much more distinct than the interior line. Hindwing slightly strewn with black. An interior and exterior line, mentioned in the original description, are not to be noticed. 30 mm. Trinidad.

24. Genus: **Asyngria** Dgn.

Antennae thick, palpi large, projecting beyond the frons. Forewing with a pointed apex, distal margin rounded. Vein 5 close below the upper cell-angle, 6 + 7 stalked, 8 + 9 + 10 stalked, 10 slightly anastomosing with 11, so that a little accessory cell is formed. Hindwing slightly angled at vein 7, then straight as far as vein 4. Veins 3 and 4 arise separately, 5 from the middle of the cross-vein, 6 + 7 stalked. Type: *nigripuncta* Dogn.

A. nigripuncta Dogn. Wings grey, striated brown. Forewing at $\frac{3}{4}$ of its length with a distinct light line *nigripuncta*. parallel with the margin, but with a deep indentation between veins 3 and 5, and with 3 black subapical spots, the upper two round, the third oblong. The same line on the hindwing is correspondingly shaped. ♂ 27 mm. Ecuador.

25. Genus: **Anorthodisca** Dgn.

The genus consists of 3 Colombian species, of which presumably only the type or the series of types are known; they are in the Un. Stat. Nat. Mus. at Washington. Figures were hardly ever supplied by DOGNIN, nor are the descriptions very clear. For characterizing the genus it is stated that the palpi are straight and project beyond the head. Antennae laminated. Vein 3 of forewing before the lower cell-angle, 5 with 6 + 7 from the same base, 6 + 7 on a short stalk, 10 close behind them, nothing is mentioned about veins 8 and 9. Hindwing dentate at veins 2, 3 and 4, then straight to the angled apex. Vein 5 not far from 4, 6 + 7 on a short stalk. Type: *albimacula* Dogn.

A. albimacula Dogn. Ground-colour brown, densely striated black, especially at the costal margin of *albimacula*. the forewing and at the anal angle of the hindwing. Forewing with a black spot at the cross-vein. Exterior line bent, very indistinct, with white dots at it between veins 6 and 1. Somewhat blackish below the apex. Hindwing also with a black cellular spot. Exterior line blackish, excurved as far as vein 4, then quite indistinct. White dusting behind it at the inner margin, and submarginal white streaks. ♂ 34 mm. Colombia. — In *impicta* Dogn. *impicta*. the marking is simplified. The striation is reduced and the colour thereby more uniform. Forewing with a single white dot between veins 4 and 5. The hindwing shows only traces of the white streaks at the anal angle. Cellular dot of forewing small, but the exterior line distinct. The interior line extends from the forewing into the cell of the hindwing. From the same habitat.

A. caesia Dogn. Hindwing obtuse at the apex. Ground-colour grey, with a lilac gloss, with black scales. *caesia*. Forewing whitish in the last third of the distal margin. A rather large black spot at the cross-vein. An exterior dark shadowy band vertical from the costal margin to vein 5, then disappearing inward. A fine white dot behind it above vein 4, and a black marginal dot above vein 6. Hindwing white at the inner margin with black streaks, finely white farther at the distal margin. ♂ 28 mm. Colombia.

A. florelineta Dogn. Ground-colour as in *caesia*. The lines on the forewing formed of shadowy bands, *florelineta*. A curved interior band. A black dot at the cross-vein. Exterior band also bent, with a series of reddish dots, finely edged with white, distinct between veins 8 and 4, less distinct from there to the inner margin. A brown marginal dot above vein 6. Hindwing black and white at the inner margin. Besides an exterior band forming the continuation of the band of the forewing, with the same dots. ♂ 30 mm. Colombia.

Genus: **Chrysocestis** Hbn.

The three species: *bisignata* Wkr., *fimbriaria* Cr. and *fimbrialis* Stoll were formerly placed to the *Epiplemidæ*. They are very much alike, so that it may be sure that not only *fimbriaria* Cr. which was lying before me, but also the two other species are *Geometridæ*.

26. Genus: **Dasmeuda** Wkr.

Proboscis short, palpi short, porrect. Antennae bipectinate. Wings broad. Forewing angled at the distal margin $\frac{1}{3}$ below the apex, then straight, oblique. Hindwing bent at the distal margin. The genus is placed here by DALLA TORRE, which is hardly justified.

alcimusata.

E. alcimusata Wkr. Brownish ochreous, striated pale brown. Forewing black at the costal margin, black are also a subapical spot and the distal margin in the anterior part; a black streak at the base of the wing. Both wings with white submarginal dots and black marginal dots. 26 mm. Amazons.

27. Genus: **Chaetoceras** Warr.

Palpi short, antennae of ♂ strongly pectinated, hind tibiae swollen. Forewing concave in the middle of the costal margin, convex near the base and apex. Apex slightly projecting, distal margin below it cut out, with a dent at veins 4 and 3, below it cut out again, anal angle angular. Veins 3 and 4 from the lower cell-angle, 5 and 6 + 7 from the upper cell-angle, 8 + 9 + 10 far back. Hindwing oblong, apex round, anal angle slightly projecting. Veins 3 and 4 from the lower cell-angle, 6 and 7 from the upper one. Type: *simplex* Warr. from Amboina. The genus contains 8 species from the Indo-Australian Fauna. Besides two South American species. Cf. Vol. X, p. 582, pl. 58 f, g.

lactifera.

Ch. lactifera Dogn. White. Forewing with black scales at the costal and distal margins. Exterior band of black dots, interrupted. Besides two black marginal dots between veins 4 and 6. Hindwing with an incomplete interior line, a black discal dot and a curved brown exterior band, with brown streaks next to it. A few dots and streaks at the costal and distal margins. ♂ 22 mm. Colombia.

versicolor.

Ch. versicolor Dogn. differs somewhat in the contours of the wings. Hindwing dentate at veins 4 and 7, excavated at 5 and 6. Ground-colour greyish brown, striated blackish brown. Forewing with an exterior row of round brown spots, edged with white scales. A subcostal spot, a few spots between veins 3 and 6 and at the inner margin. Hindwing with a brown incomplete interior line. The exterior line white, edged with brown on both sides, angled in the middle at veins 3 and 4. ♂ 27 mm. Colombia.

28. Genus: **Crypsicoela** Dgn.

Antennae thick, palpi short. Forewing with an obtuse apex. Distal margin dentate at veins 6 and 7, less at vein 4, strongly excavated between, then straight to the curved anal angle. Close before the latter the inner margin is very much cut out. Vein 4 from the lower cell-angle, 5 and 6 + 7 from the upper angle, 8 + 9 stalked. Hindwing cut out in the middle at the costal margin and at the distal margin above vein 7, with slight tips at veins 6 and 4. Vein 4 from the lower cell-angle, 6 and 7 from the upper cell-angle. Only 1 species.

subocellata.

C. subocellata Dogn. (171 c). Wings dark brown. Forewing with a rusty red spot at the cross-vein. A black line from $\frac{1}{3}$ costal margin, almost horizontal to this spot, then indistinct to the middle of the inner margin. A submarginal row of brown lunae, edged with white outside and with black behind it. A dark brown marginal line from the apex to vein 3 straight, cutting off the two notches. Hindwing with a curved interior row of black dots. An exterior row of lunar spots mostly only distinct in the anterior part. A dark marginal line from vein 7—2, corresponding to the line on the forewing. The ♀ is somewhat lighter and smaller. 26—32 mm. Bolivia.

29. Genus: **Epiplema** H.-Schäff.

Already about 300 forms of this typical genus of the family have been made known, and as the species, the majority of which is very insignificant, are generally regarded as small Geometrids or even Microlepidoptera by amateur and non-specializing collectors, they have hitherto attracted slight attention. This is principally due to the fact that they are not much attracted by light and those really rare ones gather in numbers on the lantern only on flying nights, when sometimes in the tropics 5—10 thousand lepidopteral specimens come to the light. Then the insignificant *Epiplema* of often only 1 to 2 cm wing span are lost among the swarms of *Saturniidae*, *Ceratocampidae*, *Notodontidae* and large *Noctuae* and awaken little interest. Another reason is that it was almost impossible so far to distinguish the few species which were described as there were practically no illustrations and the usually long-winded descriptions, sometimes based upon one specimen only, were scattered and hardly sufficient for a safe discrimination. The *Epiplema* have been thoroughly elaborated only in the very largest museums, and the numerous single specimens in small private collections (often placed among the Geometrids) have seldom been considered as their owners were vague as to their classification. Most of the species appear, as already mentioned, only singly and are difficult to distinguish by day, resting, often with wings furled in disguise, along wood paths on low growing weeds or bushes. Their position at rest reminds us strongly of the larger *Micros*, the *Alucitidae* for instance. If they are discovered and recognized in spite of their

disguise, many of them take refuge in the darkness of the bushes from which it is hard to drive them out. Only the *E. incolorata* (171 c) appears in places as a really common *Epiplema* though extraordinarily individual and varying locally. It may happen that in a day's catch not a single specimen resembles another, which adds to the difficulty of recognizing the species. — Altogether we specify about 70 forms of this genus from America; more than double that number are listed in Vol. X from the Indo-Australian Region. Africa has hardly more than 20 species, the palaearctic region does not even attain that number; they abound like so many other groups of *Heterocera* in the Papuan Region. — Palpi obliquely porrect. Antennae of ♂ thickened. Margins of wings very variably shaped. Forewing with veins 3 and 4 from the lower angle, 5 and 6 + 7 from the upper angle, 8 + 9 stalked. Hindwing with veins 3 and 4 from the lower angle, 6 and 7 from the upper angle. Type: *acutangularia* H.-Schäff. from South America. Cf. also Vol. II, p. 278; Vol. X, p. 583, and Vol. XIV, p. 391.

1. Forewing as well as hindwing without an excision at the distal margin.

E. rotundata Warr. (171 c). Yellow, somewhat browner at the margin. The lines brown. The interior *rotundata*. one at $\frac{1}{3}$, strongly extra-angular in the middle. The exterior line at $\frac{2}{3}$, uniformly bent, edged with brownish ochre outside. Four black dots before the margin from the apex to vein 4. On the hindwing the two brown lines are more distinct, two black marginal dots near the apex. ♂ 13 mm. Paraguay.

E. mamillata Fldr. (= *obvallataria* Mschlr.) (172 b). Tan-coloured. Forewing with two violettish brown *mamillata*. triangles edged with red-brown, one each at the costal and inner margins. Narrowly red-brown in the anterior part of the distal margin. Hindwing with a red-brown line from the middle of the costal margin towards the anal angle, bent inward at vein 3 and disappearing. The specimen figured by FELDER is somewhat greyer than the two specimens (types) of *obvallataria*. 18—22 mm. Portorico, Panama, Amazons.

E. atrilinea Dogn. Lilac grey, strewn with white atoms at the distal margin in both wings; the fore- *atrilinea*. wing especially at the end of the costal margin and the hindwing at the inner margin. Forewing with the beginnings of 3 black lines: a basal line, an interior and exterior one. Black dots at the base of the cell, at the cross-vein and above vein 6. Two white postmedian dots on veins 5 and 6. Hindwing also with 3 lines; a short one at the base, a median line as far as the large black cellular spot and an exterior bent continuous line. As nothing is mentioned about marginal dents in the description, it is placed here. ♂ 24 mm. Colombia.

2. Forewing without an excision at the distal margin, hindwing with a dent at veins 7 and 4, sometimes also at vein 6.

E. ornata Jones (172 b). Forewing greyish ochreous, greyish brown at the costal margin as far as the *ornata*. exterior line and with the apex as far as vein 3 downward in the middle. Dark at vein 2 as far as the exterior line. Interior line fine, indistinct, dark, excurved in the cell. Exterior line undulate, rusty brown, almost parallel with the margin, whitish behind it. Marginal area grey and greyish brown. Hindwing greyish ochreous. Interior line very dark, angled in the cell. Median line parallel with it. The space between dark greyish brown, a dark undulate exterior line behind it. Hindwing with but one dent at vein 6. ♂ 18 mm. Brazil. The description of the hindwing differs somewhat from the original figure.

E. ora Drc. (172 c). Ground-colour greyish brown. Exterior line of forewing uniformly bent from $\frac{3}{4}$ *ora*. costal margin to $\frac{3}{4}$ inner margin, broadly edged with reddish brown inside. Interior line marked by 2 black streaks at the inner margin. Hindwing white at the inner margin. Adjoining to it a spot in the middle and an exterior white band as far as vein 4; reddish brown above and below the latter. ♀ 24 mm. Mexico, Guatemala.

E. varipuncta Dogn. Wings white with red-brown dots. Three dots from the cell to the inner margin *varipuncta*. indicate the interior line. Exterior line indicated by 4 somewhat larger spots. A few dark streaks in front before the distal margin. Hindwing with a spot in the cell, at the costal margin, behind the cell, and with streaks before the margin. Hindwing slightly dentate at veins 4 and 7, somewhat concave between them. ♀ 20 mm. Ecuador.

E. subapicata Dyar i. l. ? (172 c). Ground-colour milky white, marking violettish brown. Interior line *subapicata*. interrupted. At the costal margin as a triangular spot vertical from the median vein, somewhat inward at vein 1. Exterior line of thick spots, two of them at the costal margin obliquely outward. Faded dark below it as far as vein 3, a white line partly indicated outside, then obliquely inward and broader dark, almost to the interior line. Blackish at the margin between veins 4 and 6. Hindwing with a median line rectangularly bent at vein 4, whitish, very broadly edged with brown inside, narrowly outside. Broadly violettish brown behind it at the margin between veins 5 and 2, a slight dent at vein 6. ♀ 22 mm. Mexico.

E. incolorata Gn. (171 c). Ground-colour from white to greyish white with a brown marking, often *incolorata*. indistinct. Median line excurved from $\frac{2}{5}$ costal margin to the middle of the inner margin, where it forms a large red-brown spot. Exterior line from $\frac{3}{5}$ costal margin to the inner margin near the anal angle. A few black dots in front at the distal margin. Interior line of hindwing notched, near the base. Exterior line from $\frac{2}{3}$ costal margin, sharply extra-angular at vein 4, then indistinct to $\frac{2}{3}$ inner margin, broadly edged with red-brown inside, with a red-brown triangle inside before the angle. A brown shadow at the margin from vein 4 upward. Brazil,

nigrocapitata. Guiana, Honduras, Portorico. — **nigrocapitata** Sn. (171 c) are intensely brown specimens indistinctly marked. Venezuela, Colombia. Presumably always together with *incolorata*. Hindwing dentate at veins 7 and 4, concave between them.

pauvillata. **E. pauvillata** Sn. Greyish brown, dusted dark brown. Forewing with 2 brown lines from $\frac{2}{5}$ and $\frac{2}{3}$ costal margin, nearing each other in the middle at the inner margin, where they form a joint spot. Four black dots in front at the distal margin. Hindwing with two brown bent lines. The notches at the distal margin are probably inexactly represented in the original figure. ♂ 14 mm. Venezuela.

excludaria. **E. excludaria** Mschlr. is just as small. Forewing ochreous, dusted with dark red-brown, no further marking being noticeable. Hindwing darker. Median area bordered by dark lines edged with light outside. Interior line rectangular in the centre of the wing, exterior line rounded off with a larger bow at vein 2. Distal margin cut out between veins 6 and 7. The only specimen preserved is unfortunately not fit for a reproduction. 14 mm. Portorico.

amorata. **E. amorata** Pack. Pearl-coloured grey. Forewing with two dark lines from $\frac{2}{5}$ and $\frac{3}{5}$ costal margin, in the beginning parallel excurved as far as vein 4, from where the exterior one extends more inward, connected with the interior line by a bar at vein 2, then the two lines separate again. Dark between veins 4 and 6 at the distal margin, edged by a brown line. Hindwing with a rounded interior line, the exterior line with a sharp outward point at vein 4, finely edged light outside. Hindwing with a dent at veins 7 and 4, a smaller one at vein 6. ♂ 20 mm. Canada, New York.

certiorata. **E. certiorata** Pearsall. Larger than *amorata*, the excision on the hindwing deeper. Dark bluish grey, dusted with black. The lines agree exactly with those of *amorata*. The median area on the forewing with black and smoke-brown scales. Hindwing with a round black spot at the margin between veins 3 and 4, dusted with blue in the exterior half; at this place the margin is not fringed, but a hair-pencil is at vein 4. The whole incision on the hindwing with a strong black marginal line. 21 mm. Arizona.

3. Differing from the 2nd group in a lobe at the costal margin of the hindwing.

rectangularia. **E. rectangularia** Jones (172 c). Brownish ochreous, the costal margin of the forewing darker. Interior line indistinct, extra-angular below the costal margin and at vein 1. Exterior line dark, faded, strongly bent inward behind the cell. Marginal area ochreous, creamy white at the apex, a violettish brown spot at the anal angle. Interior line black, rectangular in the centre of the wing, violettish brown behind it, except in the apical area. Exterior line sharply angled at vein 4. The light apical area is edged dark. ♀ 24 mm. Brazil.

4. Forewing slightly cut out at the distal margin between veins 6 and 4. Hindwing with a feeble dent at veins 7 and 4.

albiocellata. **E. albiocellata** Warr. (171 d). Forewing red-brown and grey without a distinct marking. Traces of a strongly bent exterior line at $\frac{3}{4}$. Distal margin dark in front, a dark spot in the cell. Hindwing bluish grey, somewhat yellowish at the costal margin. Interior line blackish, undulate, interrupted. Exterior line black, angled at vein 4. Cross-vein white. A fine white streak below the lower small tail. Antennae of ♂ serrate. Veins 8 + 9 + 10 of forewing stalked, vein 3 of hindwing far off from 4. ♂ 18 mm. Venezuela.

turbinata. **E. turbinata** Warr. (171 d) is just as insignificant as *albiocellata*. Pale greyish yellow. A narrow greyish brown median band, somewhat broader at both its ends, very narrow in the middle, edged with black, somewhat oblique. Submarginal band marked by dark scales. Hindwing more greyish brown. A bent dark median line. Fine black lunae at the marginal excision. Submarginal line traceable. ♂ 13 mm. Peru.

lignicolor. **E. lignicolor** Dogn. Wings wood-coloured yellow, the scanty marking dark brown. It consists of a marginal spot on the forewing between veins 4 and 6. Besides both wings are traversed by a broad median band, interrupted on the forewing, with a spur branching off at vein 4 of the hindwing, the margin of the hindwing somewhat brownish. Forewing with a hair-pencil at the anal angle. ♂ 20 mm. Colombia.

rufula. **E. rufula** Warr. (171 d). Greyish brown or reddish brown, with a darker median band. The interior border from $\frac{1}{3}$ costal margin to $\frac{1}{3}$ inner margin, extending somewhat inward at the median vein. The exterior one from $\frac{2}{3}$ costal margin to the middle of the inner margin. Distally angled at the median vein. Two black submarginal spots behind the cell. Hindwing with an indistinct dark brown median band. ♀ 20 mm. Ecuador.

bilineata. **E. bilineata** Dogn. Ground-colour reddish. The two lines on the forewing rusty brown. The interior one strongly angled in the cell, then oblique, straight. Exterior line oblique, straight, continued on the hindwing, bent at vein 2, extending to the inner margin. Between these two lines the ground-colour is lilac grey. A few black dots before the margin. Margin of hindwing slightly salient at vein 7, otherwise the species is said to be allied with *rufula*. ♂ 25 mm. Colombia.

E. obliquifascia Dogn. resembles a small *rufula* (171 d). Light reddish brown, the marking brown. Both wings with a joint median band which is broadest at the costal margin of the forewing. This band is traversed on the forewing by a thick straight dark oblique line almost parallel with the distal margin. On the hindwing the band turns darker, yellow striae are at the margin. The excision on the forewing is edged with brown. ♀ 18 mm. Colombia.

E. rectilinea Warr. (171 d). Reddish brown, the lines dark brown. Interior line of forewing from $\frac{1}{4}$ costal margin, bent over at the median vein and to $\frac{1}{4}$ inner margin. Exterior line straight, from $\frac{2}{3}$ costal margin to $\frac{2}{3}$ inner margin, the space between darker brown especially at the inner margin, also at the base of the wing. A faded spot at the margin between veins 4 and 6. Interior line of hindwing slightly bent, the exterior one more bent. ♂ 20 mm. Peru.

E. commixtata Warr. (171 d). Claret-coloured, dusted with black. Median band of forewing red-brown, edged with black. The interior border from $\frac{1}{3}$ costal margin obliquely bent outward, then vertically to the middle of the inner margin. The exterior border almost vertical, slightly excurved at the costal margin to $\frac{2}{3}$ inner margin. Blackish brown before the excision. The median band on the hindwing is much broader, extending almost to the base, edged pale outside. A black spot at the margin between veins 3 and 4. 22 mm. Peru.

E. rostrifera Warr. (171 d). Wood-brown and dark brown, the lines blackish brown. The interior one excurved from $\frac{1}{4}$ costal margin to the median vein, then vertical. The exterior one from $\frac{2}{3}$ costal margin vertical to vein 4, where it forms a feeble angle, concave above the inner margin, edged with light. Black at the margin before the excision. Hindwing paler at the base. Interior line indistinct, notched, light. Exterior line also pale, pointedly projecting at vein 4, bent inward above it and below it. Peru.

E. caesiogrisea Warr. (171 d). Slate-coloured, with dark striae at the costal margin. The lines faded, dark. The first obliquely outward from $\frac{1}{3}$ costal margin, bent to $\frac{1}{3}$ inner margin in the middle. The exterior line from $\frac{3}{5}$ costal margin rather vertical, then slightly inward, ending beside the interior line. A dark shadow from the anal angle to the middle of the exterior line. Argentina.

E. excoria Warr. Forewing grey, with dark striae at the costal margin. The transverse lines fine. The first from $\frac{1}{3}$ costal margin outward, bent in the middle of the wing, then obliquely inward. The exterior line at $\frac{2}{3}$, straight, obliquely inward. A blackish spot in the narrow interspace between veins 4 and 6. A dark submarginal shadow is traceable, the excision edged with brown. On the hindwing the lines are brown, both bent parallel. A few bluish white scales at the distal margin. Beside the excision between veins 7 and 4 of the hindwing there is another one in the submedian fold. The dents and excisions are stronger in the ♀. 18 mm. Mexico.

E. purpurata Dogn. Lilac blackish brown with a few white scales. The interior line on the forewing is hardly traceable, the exterior one reddish, black inside, strongly angled at vein 4. A black luna before the excision. Hindwing with the exterior line likewise angled at vein 4. A black dot at the margin above and below vein 4. The dents at veins 7 and 4 pointed. ♂ 23 mm. Colombia.

5. Forewing more or less cut out at the distal margin between veins 6 and 4, apex obtusely cut off. Hindwing with a dent at veins 7 and 4, a smaller one at vein 5.

E. acutangularia H.-Schäff. (= *praeclorata* Mschlr.) (171 e). Forewing of ♂ greyish brown, ♀ reddish brown. The excision at the margin not very deep. A quadrangular spot in the middle of the costal margin somewhat darker than the ground-colour, a semicircular spot above the middle of the inner margin, both distinct, edged with dark brown. A brownish shadow from the anal angle vertically upward to the costal margin. A straight black line before the excision. Hindwing of ♀ more intensely red-brown, of ♂ greyish brown. Interior line near the base, dark, rounded. Exterior line fine white, sharply angled at vein 4, then extinct to the inner margin. 28—32 mm. Brazil.

E. rubrofasciata sp. n. (172 c). ♂. Similar to *acutangularia* in the wing-contours. Ground-colour light reddish brown. Of the anterior spot only the exterior black border-line is preserved; of that at the inner margin only 2 spots above vein 1. Hindwing with the black interior line extending from $\frac{1}{3}$ costal margin vertically to the lower cell-edge. The exterior one from $\frac{2}{3}$ costal margin, obtusely angled at vein 4, to $\frac{2}{3}$ inner margin. The space between both lines in the anterior part filled with red-brown with 2 white dots. Dark dusting in the submedian fold at the margin. ♀ 26 mm. Bolivia.

E. coelisparsa Dogn. Hindwing angled only at veins 4 and 7. Ground-colour of both wings brownish ochreous, the lines dark brown. Costal margin of forewing dusted somewhat white. Interior line only from $\frac{1}{3}$ costal margin to the base of vein 3, then again as a short oblique streak at the inner margin. Exterior line almost parallel with the distal margin. Submarginal line indicated by white dusting. Interior line of hindwing twice bent, the exterior line excurved between veins 2 and 6. The whole hindwing is strewn with white, especially at the veins. ♂ 24—28 mm. Colombia.

E. ignefumata Warr. (171 e). Dark brown. Interior line of forewing black, from $\frac{1}{3}$ costal margin obliquely outward, from the median vein vertically to the middle of the inner margin. Exterior line from $\frac{3}{4}$ costal margin to $\frac{3}{4}$ inner margin, sharply angled at vein 4, incurved on both sides of the angle. The space between

blackish. Distal margin from veins 6—3 with a black luna. The median band on the hindwing violettish blackish, both the edges sharply angled at vein 4. Blackish at the margin from the apex to vein 4. A black spot at each dent. ♂ 24 mm. Peru.

ignefusa. **E. ignefusa** Warr. (171 d). Wings rusty brown and olive brown, costal margin of forewing paler. The lines indistinct, dark brown. A few near the base. The exterior line angled at vein 4. Somewhat darkened at the excision. The two lines on the hindwing more distinctly, dark brown, both angled in the middle. Between the dents black marginal lunae and a black spot below the lowest dent. The species is said to resemble *E. scabra* (171 f), which is not to be seen in the figure. ♀ 18 mm. Peru.

fulvigrisea. **E. fulvigrisea** Warr. *i. l.* (171 e). Dark rusty brown, veins and margin of forewing dark brown, a black luna before the excision. Two black dots at the costal margin indicate the beginnings of a median and exterior line. Hindwing dark reddish brown, violet at the margin. Lines black, the interior one uniformly bent, the exterior one more bent at vein 4. ♂ 20 mm. South America.

nigricans. **E. nigricans** Dogn. ♂. Wings blackish, lustrous blue, the last quarter at the costal margin and below the apex greyer, reddish at the excision. The two transverse lines only indicated at the inner margin by 2 dots each. Hindwing with 2 blackish brown lines, the interior one bent in the cell, the exterior one at vein 4, both edged with white. The ♀ is browner. Forewing with a blacker median band, the edges of which are faded, twice as broad at the costal margin as at the black dots at the inner margin. 26 mm. Colombia.

The following species show a deeper excision on the forewing.

hians. **E. hians** Fldr. (171 e). Bluish grey. Interior line of forewing thick, black, from $\frac{1}{4}$ costal margin to the lower cell-angle, then finely white, edged with black to the middle of the inner margin, extra-angular above it. Exterior line fine white, undulate, from $\frac{3}{4}$ costal margin to $\frac{3}{4}$ inner margin, slightly excurved at vein 4, broadly edged with black inside. A black submarginal line from the apex to vein 3. Interior line of hindwing black, straight, from $\frac{1}{4}$ costal margin to $\frac{2}{3}$ inner margin. Exterior line fine white, pointedly projecting at vein 4, edged with black inside. Inner margin yellowish. 28—30 mm. Venezuela. — *lucisquamata* Warr. (171 e, f) is mostly less dusted with blue, ground-colour reddish brown. Interior line dark brown, the exterior one double, blackish, filled with red-brown. Blackish between the two lines at the inner margin in the ♀. Both lines on the hindwing red-brown, finely white on the averted sides. 28—30 mm. Peru.

6. Excision on forewing strong, the dent at vein 7 on the hindwing is more salient than the one at vein 4, a projecting lobe at vein 8.

draco. **E. draco** Warr. (171 f). Lilac greyish brown, coarsely dusted dark, lighter at the apex. Interior line dark brown, very obliquely outward from $\frac{1}{3}$ costal margin, very indistinctly from the cell to the middle of the inner margin. Exterior line from $\frac{2}{3}$ costal margin vertically to vein 4, then quite indistinct, removed outward, ending at the inner margin near the anal angle. Hindwing red-brown in the interior two thirds. A yellowish brown faded median and exterior band. Margin lilac grey. 22—24 mm. Bolivia.

scabra. **E. scabra** Warr. (171 f). Rusty red, dusted with lilac grey. The forewing with a greyish yellow spot between the exterior and submarginal lines down as far as vein 5, a series of red lunae behind it at the distal margin. Interior line red, indistinct, from $\frac{1}{3}$ costal margin obliquely outward as far as the cell, then vertically to the middle of the inner margin. The exterior line almost vertically from $\frac{2}{3}$ costal margin, slightly angled at veins 6 and 4, then concave. Hindwing with a darker curved median band, finely edged with light outside. A dark spot at the lower dent. ♀ 22 mm. Peru.

vulpecula. **E. vulpecula** Warr. (171 f) resembles a large pale *scabra*. Light brick-red, dusted dark at the costal margin. A broad lilac grey postmedian band. Transverse lines indistinct, but rather similar to *scabra*. Hindwing still more indistinctly marked. Traces of a light band at the inner margin. A blackish spot below the lower dent. ♀ 24 mm. Peru.

reversata. **E. reversata** Warr. (171 f). Greyish brown, dark oblique streaks at the costal margin, without transverse lines. Distal margin broadly blackish brown. A brown spot traceable at the cross-vein. Hindwing browner, with 5 indistinct dark bands. ♂ 21 mm. Peru.

illota. **E. illota** Dogn. Greyish ochreous, marbled with greenish brown. Interior line bent at the costal margin, more intensely greenish brown, then faded. Besides a similar interrupted exterior line and a marginal line. Cross-vein spotted reddish, before the excision likewise reddish. Hindwing more reddened, the spots forming a straight exterior and submarginal band. ♂ 20 mm. Colombia.

equinata. **E. equinata** Gn. (172 c). Greyish brown, with a slight lilac reflection. Interior line black, from $\frac{1}{3}$ costal margin obliquely outward to vein 2, then vanishing. Exterior line from a black oblique streak beginning at $\frac{2}{3}$ costal margin, bent at vein 4 and parallel with the margin to $\frac{3}{4}$ inner margin. There before it a black semi-circle. The latter and the anterior space between the two lines somewhat darker brown. A brown line before the excision. Both the lines on the hindwing fine black, rectangular in the middle of the wing, the exterior one finely edged with white. Darker between them. 22 mm. Cayenne.

E. columbicolor Warr. (171 g). Forewing yellowish white. The lines very indistinct, brownish. The *columbicolor*. interior one from $\frac{1}{3}$ costal margin from a black spot obliquely outward to the cell, then to $\frac{1}{3}$ inner margin, a round dark spot behind it in the submedian fold. Exterior line from $\frac{2}{3}$ costal margin, excurved, very indistinct, ending in a spot close beside the interior line. A dark shadow from the anal angle upward to vein 4. The excision edged with dark. Hindwing more reddish. The lines rusty brown. The interior one bent, the exterior one curved at vein 4. Rusty brown at the margin between the two dents, a brown spot below it. ♂ 18 mm. Peru.

E. mixtilinea Warr. (171 g). Dark brownish grey, spotted black at the costal margin. Lines black, in- *mixtilinea*. distinct, interrupted. The interior one from $\frac{1}{3}$ costal margin, bent in the middle, indistinct, then vertically to the middle of the inner margin. Exterior line from $\frac{2}{3}$ costal margin to $\frac{2}{3}$ inner margin, interrupted in the middle. A black luna at the excision. Darker at the anal angle. Hindwing with an angular interior line, interrupted in the middle. Exterior line sharply angled at vein 4, marginal area broadly dark. In the figure, however, the two lines are uniformly bent. ♂ 20 mm. Peru. — The presumable ♀ is a little darker. The interior and exterior lines are nearing each other in front as in *draco*, whereupon they extend together fadedly inward, parting at the inner margin semicircularly. On the hindwing the faded interior line is as bent as in the figure of the ♂, the exterior line red-brown inside, whitish outside, slightly angled at veins 5 and 2. Traces of a submarginal shadow. 22 mm. Bolivia.

E. alpina sp. n. (172 d). Reddish brown with a violet shine, costal margin lighter in its exterior part. *alpina*. Interior line dark brown, faded, from $\frac{1}{3}$ costal margin obliquely outward as far as into the cell, then bent inward to $\frac{2}{5}$ inner margin. The exterior line from $\frac{2}{3}$ costal margin to $\frac{3}{4}$ inner margin, slightly inward at the two ends. Black dots behind it at the costal margin. A dark brown line at the margin, slightly stronger at the excision. Hindwing somewhat lighter at the base. Median band broad, straight, bent somewhat inward in the submedian fold, with a black spot there at the interior border, coloured like the median band of the forewing. Lighter again behind it. The margin broadly dark. No dent at vein 6. ♂ 20 mm. Bolivia, 2—3000 m (Garlepp). Type in the Berlin Museum.

E. aequidistans sp. n. (172 d). Forewing ochreous. Interior line dark brown, far excurved from $\frac{1}{4}$ costal *aequidistans*. margin, then inward to $\frac{1}{3}$ inner margin. Exterior line from $\frac{2}{3}$ costal margin somewhat obliquely outward, very indistinct, then parallel with the interior line, but from the submedian fold slightly outward; outside the exterior line is rectilinear, rusty brown, prolonged to the costal margin. The median area somewhat violet. A straight rusty brown line before the feeble excision at the margin, with a black dot above and below. Basal area of hindwing as light as the forewing. Median area as on the forewing. The interior border brown, undulate, straight; the exterior one rusty brown inside, light outside, slightly bent at vein 4. Marginal area somewhat lighter, with a black dot below the lower dent. ♂ 18 mm. Haiti. — We figure the type (in the Berlin Museum).

The following species with long dents at veins 7 and 4 of the hindwing.

E. straminea Warr. (171 g). Apex apparently pointed not truncate, as usual with an excision at the *straminea*. margin. Forewing straw-coloured, somewhat violettish brown at the inner margin. The fine grey lines are edged with brown. The interior one from $\frac{1}{3}$ costal margin to $\frac{1}{3}$ inner margin, extra-angular in the cell and submedian fold. Exterior line from $\frac{2}{3}$ costal margin to $\frac{2}{3}$ inner margin, vertical, only with a feeble outward notch at vein 4. Submarginal shadow brownish, double, indistinct, ending in a violettish black spot at the anal angle. Hindwing paler, browner at the costal margin. The two lines brown, double; the interior one sharply angled at vein 4, the exterior one obtusely, according to the description. According to the figure, however, it is just the reverse, and mostly also the exterior one is more sharply angled. A brown spot at the cross-vein is surrounded with brown. A dark submarginal line from the costal margin to the dent at vein 4. Besides two black dots at the lower dent. ♀ 22 mm. Peru.

E. pallifrons Warr. (171 g). Pale brown, costal margin lighter. Interior line from $\frac{1}{3}$ costal margin to *pallifrons*. $\frac{1}{3}$ inner margin, far outward between, extra-angular at vein 4 and in the submedian fold, dark brown. Exterior line paler, from $\frac{2}{3}$ costal margin, slightly extra-angular at vein 6, more so at vein 4, introangular at vein 2, to $\frac{3}{4}$ inner margin, with a white dot above and below vein 4. Submarginal line black, interrupted, stronger at the excision. Hindwing with a blackish bent interrupted interior line. Exterior line dark brown, sharply angled at vein 4, its anterior part thickly edged with white. Black spots edged white inside are at the margin from the upper dent to below the lower dent. ♀ 25 mm. Peru, Sa. Catharina.

E. dryopterata Grote (171 g). Hindwing straight between the dent at vein 4 and the anal angle. Ground- *dryopterata*. colour dull brownish ochreous. Median band of forewing somewhat darker. Its borders dark brown. Interior line from $\frac{2}{5}$ costal margin to $\frac{2}{5}$ inner margin, strongly excurved between. Exterior line slightly excurved from $\frac{2}{3}$ costal margin, then rather vertically to $\frac{4}{5}$ inner margin, the median area behind the interior line at the inner margin darker. Hindwing with 2 parallel brown lines which are rectangular at vein 4. 20 mm. New York, Alabama.

The following species exhibit a large excision at the distal margin of the forewing, the hindwing being rounded. It is doubtful whether they belong to the *Epiplema*.

E. ocalea Drc. (172 d). Forewing reddish brown, paler at the base. Traces of a median, exterior and *ocalea*. submarginal vertical dark brown band. Hindwing ochreous in the inner-marginal area with dark brown lines, apical area brown. ♀ 20 mm. Guatemala.

carilla. **E. carilla** Drc. (172 d). Forewing pale brown. A dark interior line from $\frac{1}{3}$ costal margin to $\frac{1}{2}$ inner margin, far excurved, and an exterior line from $\frac{2}{3}$ costal margin rather straightly towards $\frac{1}{2}$ inner margin. Hindwing pale yellow, brownish at the base. ♂ 25 mm. Guatemala.

similata. **E. similata** dalla Torre (= *similaria* Schs.) is near *carilla* (172 d). Forewing light brown, dusted somewhat dark brown, inner margin greyish brown. A dark brown line from the costal margin before the middle to below vein 4 near its base, then bent up again to the costal margin. Hindwing brownish grey, dusted with brownish ochre outside, veins 3 + 4 stalked. ♂ 24 mm. Costa Rica.

The following species lack any statements about the shape of the distal margin or their resemblance to other species.

cononaria. **E. cononaria** Schs. Wings grey slightly mixed with brown. Interior line of forewing reddish brown, excurved, touching a small brown spot below the costal margin. A large dark brown spot close behind the cell. Exterior line reddish brown, thicker at the costal margin, slightly incurved. A submarginal red-brown shadow from the apex to vein 4. Hindwing darker. Interior and exterior lines more formed of spots. Median area with blackish brown streaks which are also behind it, though not at the distal margin. 17—21 mm. Costa Rica.

lustrata. **E. lustrata** Schs. Forewing light grey, slightly dusted with black. Median line thin, light reddish brown, excurved. Exterior band reddish brown from the costal margin to vein 5, then darker grey, edged with reddish outside, reddish below vein 2, broadly edged with blackish brown, fused with the median line. A dark submarginal shadow from vein 3 to the anal angle. Reddish brown before the excision below the apex, inwardly edged with black. Hindwing greyish white at the base and inner margin, the rest reddish brown. Median line dark brown, from vein 3 to the inner margin. Exterior line angled between veins 3 and 4, white on a brown ground, brown at the inner margin. A black marginal dot below vein 4. ♂ 20 mm. Costa Rica.

chremesaria. **E. chremesaria** Schs. Forewing dark brown as far as the exterior line, hued with steel-blue, the lines brown. Median line angled at vein 4, edged with white inside from the cell to the inner margin. Exterior line edged with white outside. Distal margin light brown with a dark brown marginal and submarginal shadow. Dark brown marginal spots above and below vein 5. Hindwing similar, dark brown at the margin. Interior line bent down to the middle of the inner margin, exterior line excurved between veins 3 and 4, edged with white outside. Anal angle grey with brown streaks. Vein 5 of forewing arises somewhat deeper than usual. ♀ 24 mm. Costa Rica.

We append here a number of species described by WALKER, which are not in the British Museum, so that it cannot be decided to which of the numerous genera of the *Epiplemidae* they belong, or whether they are *Epiplemidae* at all and not partly *Geometridae*. We arrange them according to the shape of the distal margin.

1. Forewing pointed, distal margin bent. Hindwing without notches or indentations.

subtruncata. **E. subtruncata** Wkr. Greyish red, wings somewhat narrow. Forewing with some fine undulate reddish yellow lines which are edged with pale greyish yellow. Submarginal line pale greyish yellow, interrupted, connected in front with a black apical streak, cross-vein black, the lower part at the distal margin very oblique. Hindwing with more indistinct lines, the distal margin truncate at the apex. ♂ 25 mm. Brazil.

integrata. **E. integrata** Wkr. Forewing also pointed. Pale greyish reddish yellow, wings rather broad, dusted with blackish. Submarginal line brownish ochreous, indistinct, parallel with the margin, edged with faded blackish on the hindwing. Marginal line silvery white with black dots. ♀ 28 mm. Amazons.

2. Hindwing with a small indentation at the margin, forewing without an indentation, pointed at the apex only in the two first species, rounded in the others.

quadruncata. **E. quadruncata** Wkr. Greyish yellow, wings broad, finely dusted with black. Interior and exterior lines brown, indistinct, the interior line slightly bent. Exterior line oblique, almost straight, edged with pale grey outside, angled above the inner margin on the forewing, where it is edged with greyish yellow outside. A black dot at the cross-vein. Hindwing violettish grey before the margin. Distal margin of hindwing slightly excavated in front. ♀ 45 mm. Brazil.

oblivaria. **E. oblivaria** Wkr. Whitish, scantily dusted with black, fine black streaks at the distal margin. Forewing with a black spot at the cross-vein, exterior line reddish yellow, angled, costal margin strongly bent, distal margin straight. Hindwing with a blackish, strongly angled exterior line, the margin excavated near the anal angle. ♂ 20 mm. Venezuela, Brazil.

distincta. **E. distincta** Wkr. Wings rusty red, rather narrow. Forewing with a black dot at the cross-vein, with an oblique brown line outside. Close behind it a rusty red line with an irregular exterior edge; submarginal line rusty red. A black dot at the costal margin at the base and before the middle, also a black subapical spot. Hindwing with a rusty red band at the distal margin which is somewhat excavated in front. ♀ 20 mm. Brazil.

E. oppositata Wkr. Greyish brown, wings oblong, partly somewhat browner. Forewing with an exterior *oppositata*. row of black dots which are more distinct at the costal margin. Marginal dots black, costal margin straight, distal margin convex. Hindwing with blackish spots and a strongly bent white line. Distal margin hollow in the middle. ♀ 22 mm. San Domingo.

E. demptaria Wkr. Pale greyish brown and reddish brown, with 2 fine bent reddish brown lines, the *demptaria*. forewing with a straight costal margin, distal margin slightly convex. Hindwing with two pointed dents, with two black submarginal dots below the lower dent, a black streak at the cross-vein and two near the apex at the costal margin. ♀ 22 mm. Venezuela.

E. subpatulata Wkr. Brownish white, irregularly spotted rusty red. Forewing with blackish spots at *subpatulata*. the costal margin near the base. Two oblique straight rusty red lines from the costal margin to the centre of the wing. A rusty red spot at the inner margin, corresponding to the interior line of the hindwing. Hindwing with two indentations and 2 sharp dents, a jet-black spot at the second dent, with 2 rusty red lines, the interior one shortened in front, the exterior one behind. ♀ 22 mm. Brazil.

3. Forewing with an excision at the distal margin.

E. chalybeata Wkr. Brown, dusted with black. Interior and exterior lines blackish, zigzag, pale-edged. *chalybeata*. Forewing very pointed, distal margin hollow in front, feebly angled in the middle. Hindwing with a submarginal black line, distal margin feebly angled. ♀ 22 mm. Brazil.

E. ferraria Wkr. Rusty yellow, dusted black, with 2 indistinct bent lines of black dots, submarginal *ferraria*. line black, interrupted. Forewing with a long black spot at the cross-vein, distal margin shaped as in *chalybeata*. Hindwing with a small dent at the middle of the margin, truncate beside it. ♀ 17 mm. Brazil.

E. subsignaria Wkr. White, finely dusted with black, distal margin with black dots. Forewing with a *subsignaria*. brown median band, irregular, incomplete, forming a bow at the inner margin. Hindwing with an incomplete brown median line, with two short blunt dents at the margin. ♀ 17 mm. Brazil.

E. lacerataria Wkr. Reddish yellow, scantily dusted with black. Interior line black, extra-angular, *lacerataria*. interrupted. Submarginal band brown, faded, far interrupted on the forewing. Exterior line of forewing rusty yellow, undulatingly edged with grey, with a white dot outside behind the cell, with black dots at the inner margin. A bent black streak at the deep indentation at the distal margin, exterior part of the inner margin hollow. Hindwing with 3 sharp dents at the rusty yellow distal margin, a black eyespot behind the lowest dent. Exterior line black, edged with white outside, angled. Costal margin excavated in the middle and at the apex. ♀ 26 mm. Amazons.

E. parvaria Wkr. Ash-grey, somewhat reddish yellow. Wings pointed. The lines reddish yellow, fine, *parvaria*. dentate, oblique. Forewing with black costal-marginal dots, distal margin reddish yellow at the excision with white streaks. Hindwing with a black spot at the end of the reddish yellow streak, exterior line partly edged with black. ♀ 17 mm. Amazons.

E. proclivaria Schs. Similar to *lacerataria*. Body and wings brown. Forewing with a few dark streaks *proclivaria*. in the basal area. Median line dark brown, excurved in the middle, almost angular at vein 4. The exterior line is a blackish brown shadow, bent inward, edged with dark brown outside, excurved below vein 2, and edged outside with a white line. A white spot behind it above vein 4, and a small blackish brown marginal spot above vein 5. Hindwing paler at the inner margin. Interior line excurved, dark brown. Exterior line dark brown, finely edged with white outside. Distal margin projecting between veins 6 and 7. ♀ 30 mm. Costa Rica.

30. Genus: **Thysanocraspeda** Warr.

A subordinate group of *Epiplema*, which it resembles in the neurulation and the marking of the wings. It consists of 9 species all of which are known from Peru and Colombia bordering on it. The forewing is slightly cut out at the margin, the hindwing is strongly dentate at vein 7, mostly less dentate at vein 4. The ♂ shows a hair-pencil at the inner margin of the hindwing, with a groove between vein 1 and the cell, mostly containing flour-like scales. For the ♀ alone it is thus not easy to decide whether they are to be included here or in *Epiplema*. Type: *semicastanea* Warr.

Th. nudata Warr. (171 g). Greyish yellow. An indistinct median band on the forewing with puncti- *nudata*. form black edges at the costal and inner margins. Feebly darker at the excision. Hindwing somewhat browner, grey at the inner margin, the pencil at the inner margin yellowish. Black dots above the middle of the inner margin. Both wings have no coarse hair at the anal angle as in *inornata*, but there are rusty brown scales in the fold on the hindwing as in *geminipuncta*. ♂ 19 mm. Peru.

Th. inornata Warr. (171 g, h). Forewing dark brownish grey, a brown luna before the excision. The *inornata*. ♀ shows traces of a darker median band the outer edge of which is rather vertical, with an outward dent at the median vein, the inner margin is slightly bent. Coarse scales at the anal angle, extending also inward below vein 2 which is bent downward. Hindwing almost uniformly dark grey, a median band is scarcely traceable.

The ♂ hindwing shows grey coarse scales in the groove and below vein 2, the pencil at the inner margin is pale yellow. 16 mm. Peru.

- vermiculata.* **Th. vermiculata** Dogn. Ground-colour grey with black scales. Interior and exterior lines of forewing indicated by red and black scales, black scales before the excision. Exterior line of hindwing rounded, indicated by a few red scales, a straight row of streaks behind it on the veins. ♀ 16 mm. Colombia.
- intervenata.* **Th. intervenata** Warr. (171 h). Wings of ♂ greyish yellow, of ♀ greyish brown, lighter at the apex of the forewing. Interior line at $\frac{1}{3}$ of the length of the wing strongly excurved below the middle, edged with dark outside at the costal and inner margins. Exterior line at $\frac{2}{3}$, vertical as far as vein 4, then incurved, forming a truncate dent. Median area somewhat darker. Hindwing the same, besides lighter at the cross-vein. 18 to 22 mm. Bolivia.
- fulvitincta.* **Th. fulvitincta** Dogn. Grey, feebly strewn with black. Interior and exterior lines of forewing indicated above the inner margin by brown dots, at the costal margin by brown scales, in the middle by reddish yellow dusting. The two lines approach each other at the inner margin. Reddish yellow dusting before the excision, edged with black inside. On the hindwing both the lines are indicated by reddish yellow dusting. ♀ 18 mm. Colombia.
- geminipuncta.* **Th. geminipuncta** Warr. (171 h). Pinkish brown, also violettish brown, the median band darker. Interior line of forewing from $\frac{1}{3}$ costal margin to $\frac{1}{3}$ inner margin, projecting far obtusely at the median vein. Exterior line from $\frac{2}{3}$ costal margin, extra-angular in the middle, then inward as far as the submedian fold, outward below the latter. Both lines above the inner margin with black spots, intensified at the costal margin. Dusted dark at the anal angle. Hindwing of the same colouring, the angled band continuous as far as the inner margin, its exterior edge introangular at vein 2. Hindwing of the ♂ beneath with large rusty brown scales in the groove, grey scales behind them and also at vein 2 as in *squamiplaga*. 18—20 mm. Peru, Bolivia. — The name *intervenata* Warr. may only refer to pale specimens of this species.
- ochodontaria.* **Th. ochodontaria** Sn. Yellowish red. Forewing dark greyish brown in the middle, with a blackish brown luna at the distal margin. Hindwing with a broader median area, with yellow hairs at the inner margin. WARREN thinks it possible that his *squamiplaga* resembles *ochodontaria* the description of which is difficult to understand. I myself rather think that *geminipuncta* might be synonymous with *ochodontaria*. The latter is said to have an expanse of 24 mm. thus much larger than all the normal species of *Thysanocraspeda*, but the marking is rather similar in *ochodontaria* and *geminipuncta*, the dots are very indistinct also in my specimens of *geminipuncta*. ♂ 24 mm. Cucqueta.
- The two last species are somewhat less scantily marked.
- semicastanea.* **Th. semicastanea** Warr. (171 h). Ground-colour greyish white, the marking light red-brown. The forewing shows the interior border of the median band strongly extra-angular at the median vein, then obliquely inward, the exterior border rather vertical. Behind it, at some distance, a faded greyish brown band. A broad luna before the excision. Hindwing with an almost straight interior line and a slightly bent exterior line. Behind the interior line the whole space above vein 3 is red-brown. The pencil at the inner margin grey. 21 mm. Peru.
- squamiplaga.* **Th. squamiplaga** Warr. (171 h). Very pale brownish grey, the marking darker red-brown than in *semicastanea*. Interior line of forewing slightly excurved from the middle of the costal margin, then inward to $\frac{3}{5}$ inner margin. Exterior line somewhat concave between $\frac{3}{4}$ costal margin and vein 6 as well as between vein 4 and $\frac{2}{3}$ inner margin. In the anterior part the median area is incompletely filled with red-brown. A red-brown luna at the excision. A tuft of grey hair at the anal angle. Hindwing nut-brown, grey only at the base and in the submedian fold. The bent median band is somewhat darker, very indistinct, edged by a pale line outside. ♂ 21 mm. Peru.

31. Genus: **Erosia** Gn.

Contours of forewing as in *E. acutangularia*. Neuration of forewing almost exactly the same as in that species, but vein 5 arises a little farther from 6 + 7. Veins 3 + 4 and 6 + 7 of hindwing stalked, the stalk of 6 + 7 short, 5 less strong, close at vein 6. The inner margin of the ♂ exhibits a broad turned down edge with scent-hair on the upper surface. Veins 3 + 4 of the ♀ are also only short-stalked. In accordance with WARREN, only 1 species is ranged here, the other *Erosia*-species described by older authors are now mostly placed to the genus *Epiptema*.

- incendiata.* **E. incendiata** Gn. (♀ = *birostrata* Gn., *furcillata* Fldr.) (171 h, i). ♂ ground-colour reddish brown. Interior line from $\frac{1}{4}$ costal margin horizontally to the base of vein 5, thick, dark brown, after this more finely inward to $\frac{2}{5}$ inner margin. Exterior line from $\frac{2}{3}$ costal margin obliquely to vein 4, where it shows white dots, then light on, inward as far as vein 2, outward below it. The median area below vein 2 darker. The interior and exterior lines on the hindwing strongly angled, radially in the middle intensely rusty red, the inner margin yellowish white. The ♂♂ seem easily to become oily. ♀ forewing as in the ♂, but the exterior line is fine, light,

the median band slightly darker. On the hindwing the two lines are more distinct. The interior one slightly, the exterior one very strongly projecting at vein 4. Basal area and the space behind the median band lighter than the latter. 30—45 mm. Mexico to Brazil. — *veninotata* Warr. (171 i) is scarcely different.

32. Genus: **Capnophylla** Warr.

Proboscis short, palpi thin, somewhat erect, antennae of ♂ plain, tegulae long. Forewing triangular, apex very round, with a small scent-spot at the inner margin at the base. Veins 2, 3 and 4 near the lower cell-angle, 5 above the middle of the cross-vein, 6 and 7 from the upper cell-angle, 8 + 9 and 10 + 11 stalked. Hindwing of ♂ almost square. Inner margin beneath with a fold for long hairs, above at the edge with erect scales. Of the veins only 6—8 are preserved. Only 1 species.

Cap. albiceps Warr. (= *castraria* Jones) (172 d). ♂ forewing olive brown, lighter at the costal margin. *albiceps*. Median line rusty brown, dark brown outside, from the inner margin somewhat outward to the lower cell-angle, then bent inward. A white dot before it in the cell-end. Exterior line rusty brown, edged with dark brown inside, bent inward at the costal margin, otherwise parallel with the distal margin, broadly faded white behind it. Hindwing olive brown, greyish-brown in the anterior half. Interior line rusty brown, only at the costal margin. Median line angled in the centre of the wing. A few years later, also the ♀ was described by WARREN. Forewing dark chocolate brown, paler at the costal margin. The two lines darker, especially at the inner margin. Interior line strongly excurved in the middle, exterior line extra-angular above the middle at veins 6 and 4, sharply inward in the submedian fold. A black line before the margin. Hindwing lighter. Interior line dark, undulate, with a white spot at the costal margin. Exterior line fine white, bent, a dark brown shadow before it, with white scales outside at the inner margin. A long dent at veins 4 and 7 at the distal margin, a short one at vein 6. 20—23 mm. Brazil. A ♂ from the Senckenberg Museum is much darker and, owing to the indistinct marking, not so well fit for being figured as the light type. The ♀, likewise from the Senckenberg Museum, differs rather much from the description quoted above. The lines on the forewing are still more indistinct than in the ♂. On the somewhat lighter hindwing both the lines are dark, bent parallel, the exterior one from $\frac{2}{3}$ costal margin to $\frac{3}{4}$ inner margin. And the main difference is the hindwing being so uniformly rounded that it is not probable that dents have been shed. Thus, in general, the ♀ figured by us fits much better to the ♂ than the ♀ described by WARREN.

C. semibrunnea Dogn. Forewing brown, intensely dusted with black, dusted somewhat red-brown in *semibrunnea*. the middle, besides a broad red-brown submarginal band. Hindwing red-brown with a bent fine interior and exterior line. ♀ 18 mm. Guiana. It is possible that it is a small *albiceps*-♀ from my point of view, not WARREN's.

33. Genus: **Philagraula** Hulst.

Palpi thin, obliquely held, antennae flattened. Forewing with a round apex, distal margin straight. Veins 3 and 4 near the lower cell-angle, 5 near the upper angle, 6 + 7 and 8 + 9 stalked. Veins 3 and 4 of the hindwing from the lower angle, 6 and 7 from the upper angle. Costal margin with a projecting lobe at the base. Distal margin with dents at veins 4, 6 and 7. Only 1 species.

Ph. slossoniae Hulst. Wings violettish brown, more brownish ochreous in the interior halves. Forewing *slossoniae*. with traces of 2 fine basal lines. A broad triangular blackish spot at the middle of the costal margin, its apex extending downward $\frac{1}{3}$ of the width of the wing. An opposite spot at the inner margin extends to $\frac{1}{4}$ upward, both being edged with a deeper black. A dark marginal spot from below the apex to the middle of the distal margin. Hindwing with a jet-black spot at the base in front. Median line reddish brown, edged with brownish ochre outside. ♂ 25 mm. Florida.

Genus: **Powondrella** dalla-Torre.

P. cingillaria Geyer. The original figure seems to me to be an *Epiplema nigrocapitata* Sn., but without having a reliable specimen nothing definite can be said about it.

34. Genus: **Symphytophleps** Warr.

Forewing oblong, apex truncate, distal margin very oblique, inner margin excurved at the base, anal angle rectangular. Vein 2 far before the cell-angle, 3 + 4 on a long stalk, 5 from the middle of the cross-vein, 6 and 7 from the upper cell-angle, 8 + 9 on a long stalk, 10 on a short stalk with them. Hindwing cut out in the middle, projecting far at veins 7 and 6, with short dents. Vein 2 far basad, 3 + 4 on a long stalk, 5 from the middle of the cross-vein, 6 and 7 from the upper cell-angle, 8 excurved at the base. Only 1 species.

S. latifascia Warr. (171 i). Greyish yellow with blackish lines. Interior line of forewing thick, far ex- *latifascia*. curved from $\frac{1}{4}$ costal margin, forming a spot there, then to $\frac{1}{3}$ inner margin, parallel with the distal margin. Exterior line somewhat excurved from $\frac{3}{4}$ costal margin, then to $\frac{4}{5}$ inner margin, blackish brown between the

two lines at the inner margin. On the hindwing the dark interior line extends from $\frac{1}{4}$ costal margin almost to the middle of the inner margin, bent inward below the cell. A black spot at the upper cell-angle. Exterior line undulate, uniformly and far excurved. The space between them darker. The ♀ shows an almost blackish ground-colour, the forewing is faded yellowish brown only in the middle before the curve of the interior line. Median area of hindwing black, the marginal area dark rusty brown. The beginnings of the two transverse lines at the costal margin of the forewing are very indistinct in the ♂ and ♀. 35—40 mm. Peru, Colombia.

35. Genus: **Antiptecta** Warr.

Palpi short, antennae flattened. Forewing with a straight costal margin, the apex rounded. Vein 5 almost from the middle of the cross-vein, 6 + 7 on short stalks, 8 + 9 stalked, 11 anastomosing with 12. Costal margin of hindwing strongly bent forward, veins 6 and 7 from the upper cell-angle, the other veins hidden in the fold at the inner margin containing a hair-pencil. There are no statements about the neurulation of the ♀ which, of course, has not this fold. Type: *pusilla* Warr. The 7 species belonging to this genus are small and of a dark colouring.

caesia. **A. caesia** Warr. Blackish slate-coloured, the lines darker. The interior line of the forewing excurved in the middle, the exterior one excurved in front, inwardly angled in the submedian fold, where it approaches the interior line, then excurved again. A black spot at the inner margin between the two lines. A black line at the distal margin from the apex to vein 4. Both the lines on the hindwing black, bent, the median area darker than the rest, the exterior line edged light. Hindwing of ♂ and ♀ dentate at veins 7, 6 and 4, the fold in the ♂ with white hairs. 16 mm. Mexico.

cinerascens. **A. cinerascens** Warr. (173 a). Greyish yellow, the ♂ paler. Distal margin of forewing somewhat reddish. Interior line at $\frac{1}{3}$, extra-angular at the median vein. Exterior line from $\frac{2}{3}$ costal margin obliquely outward as far as vein 6, then vertical as far as vein 2, then undulate to $\frac{3}{4}$ inner margin, median band dark brown. In the ♀ this band is complete, in the ♂ narrower below the middle and interrupted. Black dots in front at the distal margin. Interior line of hindwing extra-angular in the middle, the exterior line from $\frac{3}{5}$ costal margin to the anal angle, bent between. The lines on both wings brown, edged with light. The ♂ shows the angle of the interior line filled with reddish grey. Hindwing of ♂ concave between veins 3 and 4, the ♀ with small dents at veins 7—3. Hair-pencil of ♂ pale ochreous. 16 mm. Cayenne.

pusilla. **A. pusilla** Warr. (172 d). Similar to *cinerascens*. Greyish brown. Forewing darker at the costal margin, the marginal third somewhat lighter. Exterior line strongly excurved above the middle, then inward to vein 2, then vertical. Interior line very indistinct, at $\frac{1}{3}$, obtusely introangular in the middle. Black dots before the margin. Hindwing only with a rusty brown exterior line, from the middle of the costal margin to $\frac{3}{4}$ inner margin, where it is broader. The fold grey with a black spot. A fine dent at veins 7 and 6. ♂ 15 mm. Dominica.

ineptaria. **A. ineptaria** Mschlr. (172 e) is a simplified *cinerascens*. Forewing dark brown with a violet reflection. As to the marking only the rest of an exterior yellow line vertical on $\frac{3}{4}$ inner margin is recognizable, extending to vein 2. Hindwing dark reddish brown. Exterior line light, straight, from behind the middle of the costal margin towards the anal angle, bent over to $\frac{3}{4}$ inner margin in the submedian fold. ♂ 16 mm. Portorico, Haiti.

clipearia. **A. clipearia** Schs. Wings light brown, dusted dark. Costal margin of forewing dark grey as far as the exterior line. A dark brown line from before the middle of the costal margin outward as far as below vein 3, then bent up again to the costal margin, where it turns slightly inward, edged with greyish white outside in the upward bend. A correspondingly bent line at the inner margin, its interior space darker. A black undulate line at the margin, with greyish white streaks inside. Hindwing broadly greyish black in the middle, bordered outside by a brown line which has white streaks outside. A pale brown shadow at the inner margin before the brown interior line. Grey and white streaks at the margin. Veins 6 and 7 on forewing arise from the same place. ♂ 15 mm. Costa Rica. Later on *clipearia* was declared by SCHAU to be identical with *nigripleta* Warr., but the description is very different.

nigripleta. **A. nigripleta** Warr. Greyish flesh-coloured, the marking similar to *cinerascens* ♂. Base of forewing pale, the exterior edge of the median band more distinctly light-edged. Hindwing with a less bent exterior line, the basal area before it blackish, except at the inner margin. ♂ 15 mm. Mexico.

triangularis. **A. triangularis** Warr. Stone-grey, dusted darker. The lines on the forewing fine, blackish, the interior line extra-angular in the middle, the exterior one angled at veins 6 and 3, often a dark shadow before it. Median area at the inner margin dark. A dark submarginal shadow at the costal and inner margins, and a fine black marginal line in the anterior part. Exterior line of hindwing bent, blackish before it, the interior line very fine. A grey submarginal shadow. Hindwing of ♂ concave before the fold which contains yellow mealy scales, in the ♀ the margin is dentate at veins 7, 6 and 4. 15 mm. Mexico.

36. Genus: **Dirades** Wkr.

Nearly all the *Dirades* are very small lepidoptera which do not differ much from the real *Epiplema* in their shape and colour. Only very few, but among them the typical species, have become known from Africa, and the geno-type *theclata* has been figured in Vol. XIV, pl. 67 h. More than 30 forms are Indo-Australian,

and a large number of species occur especially in Ceylon and the Sunda Is.; more than a dozen forms have been reported from Ceylon alone. Only two American species occur in the genus as it is comprehended here, a very tiny one the smallness of which is only excelled by *Epipyropidae*, and a larger one which is rather unicoloured sooty blackish brown. — Palpi erect, reaching the frons. Wings broad. Vein 5 of forewing below the upper cell-angle, somewhat higher than in the preceding genus, all the other veins the same. Hindwing typically with small points at veins 7 and 4. Vein 5 from the middle of the cross-vein, 6 and 7 from the upper cell-angle or on a short stalk. ♂ with a fold and hair-pencil at the inner margin beneath. Type: *theclata* Gn. from Africa and India. *Dirades* is one of the few genera occurring in several faunae.

D. infans Warr. (172 e). Wings lilac grey, dusted darker. Median band of forewing brownish, thickly edged with dark brown. Interior line at $\frac{1}{3}$, uniformly bent, the exterior line from $\frac{3}{4}$ costal margin, outward as far as vein 6, then vertical to vein 4, bent inward in the submedian fold. A dark shadow behind it at the costal margin and anal angle. Black dots before the margin. Hindwing similar. Both the lines bent, marginal area silvery grey, a black dot before the lower dent. Inner margin of forewing excurved at the base, hollow behind the middle. Hindwing with a dent at vein 4, smaller ones at 6 and 7. ♀ 12 mm. Jamaica.

D. erebata Warr. (172 e) has the neurulation of *Dirades*, but it looks quite different. Brownish black. A black line at the cross-vein of the forewing, a white spot before it. Exterior line pale, edged darker inside, from $\frac{4}{5}$ costal margin somewhat outward, from veins 6—2 vertical, then inward almost to the anal angle. The hindwing has a dark bent exterior line, with rusty brown scales behind it and pale spots between the veins. Inner margin and fold white, the hair-pencil brownish ochreous. ♂ 23 mm. Peru.

37. Genus: **Gathynia** Wkr.

This genus has also been differently defined by the various authors. It occurs especially in the Indo-Australian Region, from where 16 forms are known; only 1 species is known from Africa and 6 from America. In the Old World, however, its distribution is enormous, extending even to the remote South-Sea Islands, and one form (*fasciaria* Leech) is said to reach also the palaearctic region in Corea. All the species are small. — Palpi thin, obliquely raised, antennae flattened. Forewing broad, entirely margined. Veins 5, 6 and 7 close together or 6 + 7 on a short stalk, 8 + 9 and 10 + 11 stalked. Hindwing concave at the costal margin in the middle, with a hair-tuft at the base and apex. Distal margin somewhat dentate at veins 7, 6 and 4, ♂ with a fold and hair-pencil at the inner margin. Neurulation of hindwing normal. Type: *misaria* Wkr. from India. Nearly all the American species resemble *dilacerata* Gn.

G. dilacerata Gn. (172 e). Forewing greyish yellow, more densely dusted dark in the anterior half, with transverse rows of dark brown spots. Hindwing blackish, whitish at the apex, yellowish at the inner margin. Three black spots at the apex. Short dents at veins 7, 6 and 4. 20 mm. Cayenne.

G. biocellata Warr. (172 e). Forewing dull greyish brown, strewn with dark. The only marking consists of 3 small black spots below the apex, the margin is narrowly brown from the apex to vein 5. Hindwing blackish. Interior line near the base, black, bent. Exterior line double, roundly bent forward in the centre of the wing, with black spots inside, edged light outside. Two white dots at the cross-vein. Black lunae at the dents. A hyaline spot at the base with black marginal streaks. ♂ 16—18 mm. Peru, Bolivia.

G. cassata Warr. Reddish grey, more brownish ochreous towards the apex. Costal-marginal area excepting the apex as far as the middle of the cell grey with brown spots. From $\frac{4}{5}$ costal margin a grey undulate line extends vertically to vein 6, where it is interrupted, at $\frac{3}{4}$ inner margin as a double black line filled with brown. Paler behind it, blackish brown only at the anal angle. Black dots before the margin. On the hindwing the apical area above vein 6 and the inner margin are pale straw-coloured. The two lines angled in the middle, the interior one black, the other one light brown. A brownish ochreous spot at the upper cell-angle. Brown and blackish brown scales from the costal margin to vein 2. Black lunae at the margin from veins 7 to 4, brown scales before them. ♀ 21 mm. Mexico.

G. ochripennis Warr. Greyish brown, brownish ochreous at the apex, costal margin spotted light and dark. A double grey undulate line from $\frac{3}{4}$ costal margin to the cell, then interrupted and as a double brown streak at the inner margin, the sides of it, however, not parallel as in *cassata*. A short greyish yellow band behind it. Anal angle dark grey. Hindwing marked as in *cassata*, but the light places ochreous, somewhat grey. A spot between veins 4 and 5 before the margin, a small cellular spot and one at the costal margin before the apex purely yellow. ♀ 24 mm. Mexico.

G. latonaria Schs. Wings rusty brown. Forewing broadly dark grey at the costal margin. Interior line fine brown, extra-angular at vein 4, forked at vein 2 and enclosing a broad dark spot at the inner margin. Exterior line dark brown, excurved, united with the interior line below vein 2. Blackish dusting at the margin and before it. A small black spot at the apex, and one below it. Hindwing scantily dusted with black, the lines

dark brown. The interior one twice excurved, the exterior one incurved, edged with white scales outside. Margin narrowly dark, with a black spot below vein 4. Veins 10 and 11 of forewing not stalked. ♀ 18 mm. Costa Rica.

orbiferata.

G. orbiferata Warr. (172 e) in the shape of the wings and in the marking does not resemble the other species of *Gathynia*. Forewing dark violettish brown. A bent dark median line is traceable. Exterior line at $\frac{3}{4}$ costal margin, dark brown, excurved as far vein 6, then parallel with the margin, somewhat inward below vein 2. Hindwing reddish brown, with a dark bent median line. Hindwing rounded at the distal margin, without dents. ♀ 19 mm. Peru.

38. Genus: **Gymnoplacia** Warr.

Similar to *Dirades*, but there is no hair-pencil in the fold of the ♂ hindwing, but a short hair-tuft at the base at the inner margin. A large hyaline spot in the base of the cell, the costal margin slightly undulated, without hair. Vein 11 of forewing nearing 12 as in *Epiplima*, but not fused with it. Only 2 species.

brevicens.

G. brevidens Dogn. (172 f) is somewhat similar to *Ep. acutangularia* (171 e), but smaller, and the forewing almost lacks the excision, on the hindwing the dent at vein 7 is not longer than the one at vein 4. Greyish yellow, strewn with black scales. Forewing with 2 large spots opposite to each other, edged with dark brown, filled with violet. A violet shadow at the anal angle, brown at the margin between veins 6 and 4. Hindwing with 2 sharply angled lines, the interior one less distinct. A black spot at the margin between veins 3 and 4. 22—24 mm. Venezuela.

anodontia.

G. anodontia Dyar has been described as an *Epiplima*, but as it is compared with *brevicens* (172 f), we place it here. Wings grey with a brown reflection. Interior and exterior lines of forewing interrupted and transformed into a large triangle at the costal margin, as well as a thick bow at the inner margin. A straight dark line is at the margin between vein 3 and the apex. Lines of hindwing irregular, bent parallel. 18—20 mm. Described according to a couple from Costa Rica and Mexico.

39. Genus: **Neodirades** Warr.

Little different from the genus *Dirades* Wkr. which is chiefly distributed in the Old World. Vein 11 of forewing strongly fused with 12, vein 5 arises a little above the middle of the cross-vein. A small scent-spot below vein 1 near the base in the ♂ and ♀. In the hindwing of the ♂ the inner margin is folded, and there is no hair-pencil in the groove. Only 1 species, in the marking quite different from *Dirades*.

spurcata.

N. spurcata Warr. (172 f). Light greyish brown, the median band somewhat darker, twice as broad at the costal margin as at the inner margin, broadly edged with white. An interrupted black line from the apex to the anal angle. Hindwing of ♀ similar to the forewing. In the ♂ the whole hindwing is white above vein 5, with a dark exterior line in it. The inner-marginal half is blacker. 15—17 mm. Peru.

40. Genus: **Neoplema** Warr.

The only species looks like an *Epiplima*, the neurulation is also similar. Veins 3 + 4 and 6 + 7 of the hindwing, however, rise on short stalks. The main difference consists in the antennae showing one row of pectinations.

candidata.

N. candidata Warr. (172 f). Yellowish white, densely dusted with brown. Interior line of forewing marked by three black dots, vertically below each other as far as into the submedian fold, besides a dot at the upper end of the cross-vein. Exterior line marked by a bent row of spots. A spot below the costal margin, two at veins 4 and 2 at the inner margin, the last 4 uniform, edged with rusty brown inside. A bent black line before the excision, a few brown spots before the margin. Hindwing with a blackish indistinct interior line. Exterior line white, edged with brown inside, straight as far as below vein 4, far outward, then dentate to $\frac{2}{3}$ inner margin. A few spots behind it at the costal margin and 2 below the lower dent. ♀ 20—22 mm.

deruptaria. Peru, Bolivia. — **deruptaria** Dyar (i. l.) (173 a). Lines only indicated yet by small shadowy spots. Mexico.

41. Genus: **Notoptya** Warr.

Also similar to *Epiplima* in the neurulation. Vein 5 of forewing arises a little below the upper cell-angle. In the ♂ the distal margin extends at vein 2 inward on $\frac{1}{3}$ its length parallel with the costal margin, the inner margin projects towards the base in a lobe. The distal margin is concave behind the cell. Only 1 species.

fuscularia.

N. fuscularia Warr. Reddish yellow with dispersed dark scales. Lines of forewing fine. Interior line indistinct, extra-angular in the middle. The exterior line from $\frac{2}{3}$ costal margin vertical to the middle, then obliquely inward, parallel with the interior line. Marginal area paler, a dark spot at the anal angle. 4 black dots in front at the distal margin. Hindwing with a bent exterior line and traces of an interior line. Two black dots before the dents. ♂ 14 mm. Brazil.

42. Genus: **Nyctibadistes** Warr.

Similar to *Gathynia*. Forewing entirely margined. Veins 2 + 3 stalked, 4 close beside from the lower cell-angle, 5 from above the middle of the cross-vein, 6 and 7 from the upper cell-angle. 8 + 9 and 10 + 11 stalked. A large scent-spot at the base in both sexes. Hindwing somewhat angular at vein 7, anal angle somewhat lobate in the ♂, vein 2 terminating into it, anal angle only humped in the ♀. Type: *informis* Warr.

N. informis Warr. (172 f). Reddish brown. Forewing with an indistinct brown median line. Exterior *informis*. line dark brown, at $\frac{3}{4}$ of the length of the wing, uniformly bent. Brown dots before the margin. Hindwing similar, the median line strongly excurved below the cell. Both wings with an indistinct cellular spot. 13 mm. Peru. — Without our figure the ♂ cannot be recognized from this description which is to refer to both sexes.

N. nigrata Warr. (172 g). Forewing dull black. Cellular spot deeper black. Three black dots before *nigrata*. the distal margin below the apex, somewhat paler before them, without any other marking. Hindwing with 2 thick dark lines. Interior line angled in the middle, close before the exterior line which is uniformly bent at $\frac{3}{5}$, the space between being black, with a few red-brown scales at the median vein. A paler spot at the apex, the fold and inner margin pale yellow. Forewing oblong, anal angle projecting. Costal margin of hindwing excavated in the middle, hairy at the apex. ♂ 19 mm. Peru.

43. Genus: **Neodeta** Warr.

Forewing oblong, costal margin straight, distal margin dentless, the inner margin bent, in both sexes a scent-spot above the base of the submedian fold. Veins 2 + 3 stalked, 5 near the middle of the cross-vein, 6 — 7 stalked, 8 + 9 stalked, 10 and 11 free. Hindwing concave in the middle of the costal margin, apex obtuse, a dent at vein 7, distal margin straight, anal angle rounded, projecting. Neuration normal. Type: *ochriplaga* Warr.

N. fasciata Warr. Violetish grey. Forewing without an interior line, the exterior one at $\frac{3}{4}$ of the *fasciata*. length, vertical as far as vein 1, bent inward at the costal and inner margins, thick black, extending somewhat inward at the veins. Broadly pinkish white behind it, striated grey at both the ends. Marginal area darker again. Hindwing with a bent interior and exterior line, the latter introangular at vein 7. The pale band behind it narrower than on the forewing, the base also pale. A tricuspid black streak in the dark marginal area from the costal margin near the apex. ♀ 15 mm. Guiana.

N. nana Warr. Forewing violetish black, a thick black interior line traceable at the inner margin. *nana*. Exterior line at $\frac{3}{4}$, rather distinct, strongly excurved in front, near the inner margin parallel with the interior line. A dark shadow before the distal margin. Hindwing with a dark bent exterior line finely edged with light. ♂ 14 mm. Guiana.

N. ochriplaga Warr. Forewing dark brown, without any markings, only three black dots at the distal *ochriplaga*. margin below the apex. Hindwing the same, with a narrow bent median band edged with dark inside, somewhat undulatingly edged outside. On either side of it paler with brownish ochreous scales which are condensed into a spot at the costal margin near the apex, with a black tricuspid line behind it. The fold is white. ♂ 17 mm. Brazil.

44. Genus: **Aphyodes** Warr.

Palpi short, proboscis small, antennae laminated. Forewing broad, costal margin straight, the apex obtusely projecting, the distal margin below it slightly concave. Veins 2 and 3 close together, before vein 4 the median vein is strongly bent upward. Vein 5 below the upper cell-angle, 6 + 7 and 8 + 9 stalked. Hindwing very small, pointed at the apex, cut out at the anal angle, the inner margin shortened and wrinkled. Veins 5 + 6 stalked, 7 and 6 far off from 8, the other veins cannot be ascertained. Only 1 species.

Aph. pilosa Warr. (172 g). Forewing reddish yellow and brown. The lines brown, thick and faded. In- *pilosa*. terior line from $\frac{1}{3}$ costal margin, bent in the cell and then to the middle of the inner margin. Exterior line from $\frac{3}{5}$ costal margin, sharply extra-angular at vein 6, then inward, ending near the interior line. Somewhat darker before the excision, also at the apex. Hindwing covered with long blackish brown hair. ♂ 19 mm. Peru.

45. Genus: **Lophopygia** Warr.

Antennae thick, palpi porrect, short, proboscis present. Abdomen with a hanging hair-tuft at the base, hind tibiae thickened. Forewing with a straight costal margin, bent at the apex, then truncate as far as vein 7, somewhat angular at veins 7 and 6. Veins 3 and 4 close together, 2 a little back, 5 and 6 + 7 from the upper cell-angle, 8 + 9 on a long stalk. Hindwing with an excision in the middle of the costal margin, the apex cut off from vein 8 to 7, an angle at 7, then bent to the anal angle. Veins 3 + 4 stalked. Only 1 species.

L. griseata Warr. (172 h). Greyish yellow with a violet reflection. Lines of forewing thick, black. The *griseata*. interior one from $\frac{1}{3}$ costal margin to $\frac{2}{5}$ inner margin, obtusely angled at the cell-end. Exterior line from $\frac{2}{5}$ costal margin to $\frac{3}{4}$ inner margin, bent inward below the middle, intensely black only below vein 2. Median

area darker brown, fadedly extended towards the anal angle. Hindwing with a somewhat darker undulate interior and exterior line, from the latter a shadow to the anal angle. ♂ 29 mm. Peru. — *Nedusia castra* (172 g) which we mentioned as a doubtful *Nedusia* on p. 1143 seems to be extremely similar. The anal angle of the hindwing, however, shows an excision which is absent in *griseata*, but the marking is at any rate more like that of *Lophopygia*.

46. Genus: **Lophotosoma** Warr.

Similar to the genus *Thysanocraspida* (p. 1161) in the wing-contours, but both the wings are more oblong. Hindwing at the anal angle with a lobe and a fold which is filled with rough scales beneath. Costal margin undulate. Neuration as in *Epiplema*. The penultimate abdominal segment exhibits hair-tufts which being turned upward meet on the dorsum. Only 1 species.

ustanalis.

L. ustanalis Warr. (172 h). Forewing lavender-green, partly darker, with claret-coloured streaks between the veins. An oblique red line from $\frac{1}{3}$ costal margin to the median vein seems to form a triangle with another one from $\frac{2}{3}$ costal margin obliquely inward. Three red streaks at the distal margin before the excision. Traces of a submarginal line of dark dots. Hindwing rusty red, spotted dark. Median band edged darker. A dark spot at the margin between veins 3 and 4, another one at the anal angle. ♂ 20 mm. Peru.

47. Genus: **Paurophlebia** Dgn.

Palpi short, hind tibiae with one pair of spurs. Forewing very oblong, apex not very prominent, distal margin slightly angled at vein 3. Veins 2 and 3 before the lower cell-angle, the cross-vein bent upward to the origin of vein 4, where it disappears. 5 near the upper cell-angle, 6 + 7 and 8 + 9 stalked. Hindwing very small, rounded. Veins 3 + 4 and 6 + 7 stalked. Only 1 species.

obscura.

P. obscura Dogn. Forewing olive brown, finely strewn with white. The interior and exterior lines only marked by a few reddish brown spots below the costal margin. Hindwing greyer. ♂ 20 mm. Colombia.

48. Genus: **Molybdophora** H.-Schäff.

Palpi projecting obliquely, antennae of ♂ with one row of pectinations, plain in the ♀. Forewing broad, apex obliquely truncated as far as vein 6. Anal angle sharp, inner margin excurved. Vein 2 bent downward, before the angle, veins 3 and 4 from the lower cell-angle, 3 slightly bent downward. 5 near the upper cell-angle, 6 + 7 from the side of the areole, 8 + 9 from its apex, 10 from the costal margin. Hindwing somewhat angular at vein 4, anal angle rectangular. Veins 3 + 4 on a short stalk or from the same base, 5 at $\frac{1}{3}$ distance from the upper cell-angle, 6 + 7 on a very long stalk. Type: *concinularia* H.-Schäff. As no other *Epiplemid* genus has an areole, *Molybdophora* may be placed here only with a reservation.

concinularia.

M. concinnularia H.-Schäff. (172 h). Ground-colour variable: yellow, greyish yellow, reddish brown, finely dusted with dark. Near the apex below the costal margin sometimes blackish scales or a rusty red stripe through the cell, also a submarginal lead-coloured line may be traceable. Black dots at the margin especially near the apex. Hindwing with submarginal dots with a white halo. 22—25 mm. Venezuela, Surinam, Amazons.

schedata.

— **schedata** Fldr. has the normal yellow ground-colour of *concinularia*. The space above the median vein on the forewing and vein 3 as far as the costal margin suffused with grey. Hindwing with a large black spot at the cross-vein. A similar one may be in *concinularia* between veins 2 and 3 behind the cell-angle. 25 mm. Amazons. — A large form (28 mm) is before me from Bolivia. Greyish white. A rusty brown stripe extends from the inner margin near the base to the margin at vein 6. Three white streaks before the margin above the stripe. The space towards the costal margin is tinged with violet. The margin between veins 6 and 3 broadly black. Hindwing with a rusty yellow line before the submarginal dots. Another species of the same size has the ground-colour of *Falcinodes rufula* (171 b).

concinularia.

M. concinnularia Hbn. (172 g) shows the forewing uniformly bent at the distal margin. The areole is very small. Vein 2 is very strongly curved in the ♂, a fold with scent-scales below it. In the ♀ vein 2 is straight. The angle at vein 4 is hardly traceable on the hindwing. Ground-colour violettish grey, dusted dark. Both wings with black dots before the margin, more or less surrounded with lead-colour. The ♀ shows this marking more distinctly, and besides a dark brown exterior band on both wings, that of the forewing being often edged with lead-coloured grey outside. 20—25 mm. Guiana, Brazil.

Alphabetical List

of the original descriptions of the American forms of *Epiplemidæ*.

* signifies that the form is also figured at the place quoted.

18. Family: **Cymatophoridae.**

Since our elaboration of the *Cymatophoridae* of the Old World, very much has been written about their relationship to the other Heterocera families established since and about their relations to the genera *Axia* and *Diloba*, with hardly any success in solving this question. Most of the discussions on these relations result in the statement that the comprehension of the three groups of *Cymatophoridae* (sensu angust.), *Epicimelia* and *Diloba* maintained in our Vol. II is incorrect and therefore untenable. But WARREN who opposes the *Axiinae* as a special (3rd) group to the *Thyatirinae* and the *Palimpsestis*-group, as well as my arguments (in Vol. II, p. 332, and in Suppl. Vol. II, p. 194) only speak of a very loose connection — if any at all — between the *Cymatophora*, *Axia* and *Diloba*, and already the remark in Vol. II that *Diloba* “scarcely belongs to this place” clearly indicates that a union with the *Cymatophoridae* is almost out of the question. In the meantime it has been recommended to establish separate families for the two groups appended to the Cymatophorid chapter in Vol. II: *Axiidae* by H. REBEL and *Dilobidae* by CLOSS & HANNEMANN. If this separation as special families has not yet been employed in the “Macrolepidoptera”, it is because further studies may nevertheless cause them to be inserted in or appended to some other Heterocera family, for which reason it appears to be more advisable in a work of reference as the present one is to leave them at their old place until this question will have been ultimately decided.

Meanwhile also the position of the genuine *Cymatophoridae* has been frequently treated upon again. The American species prove to be rather homogenous among themselves and still more connected with the palaearctic forms than with those of the other faunae. We find the European *Thyatira batis* represented by quite similar forms across a very great part of America, especially also in its tropical regions, and the same is the case with *Habrosyne derasa*; and the representatives of these two genera so truly resembling the palaearctic ones appear in America even in their largest and most beautiful forms, i. e. *Thyatira mexicana* and *H. scripta* which shows a wonderfully delicate colouring. Also the eastern palaearctic *trimacula* is represented in Tropical America by the wonderful *Th. heurippa* which, in a certain measure, connects the colouring of *Thyatira batis* with that of *Habrosyne derasa*.

Many of the 250 names in DALLA TORRE's “Lepidopterorum Catalogus” simply denote insignificant deviations or also only synonyms; frequently forms have been named, which scarcely differ from their nomenclatural type, as for instance *Cymatophora ab. albingensis* from the typical *or.* And yet the transformation of the type into its melanism has taken place, so to speak, before our eyes; and this process seems to be in full swing just now (cf. Suppl. Vol. II, p. 197). The total number of the well separable species of *Cymatophoridae* probably amounts to about 100 one third of which occur in America.

Another species was recently established for America, showing a few remarkable characteristics of the *Cymatophoridae*, i. e. *Oiozona geometrica* Draudt, which was similarly to be appended to the other genera of the family. However, its character proved to be that of the *Notodontidae*, for which reason the species has been treated there and figured on pl. 154 b. Neither would its insertion in the *Cymatophoridae* have shown a connecting link between the *Notodontidae* and the *Cymatophoridae*, so that the latter still have no definite position in the system. SICK, in a recent publication, refers to the resemblance of the tympanal organ to that of the *Drepanidae*.

1. Genus: **Habrosyne** Hbn.

All the important details about this genus have been mentioned already in Vol. II, p. 322. Only 2 or 3 species occur in the American Region, thus not even as many as in the Palaearctic Region. Type: *derasa* L. from Europe.

scripta.

H. scripta Gosse (172 h). Similar to *derasa* (Vol. II, pl. 49 d). Thorax and forewing bronze brown. At the costal margin near the base there is a white triangle from which a short white streak extends obliquely inward to vein 1. An oblique line extends outward from this triangle to a little beyond vein 1, then it bends inward to the inner margin. Ring-macula and reniform macula close together, edged with white, the latter with a white median streak. White before it at the costal margin almost as far as the apex. An exterior white line is only shortly traceable at the costal margin and at the inner margin from vein 2. Numerous parallel strongly dentated dark and light lines behind the reniform macula and down as far as the middle of the inner margin. Submarginal line thick, white, from the apex to the anal angle, bent inward between them. Hindwing brown, lighter at the base, with traces of a light exterior line near the inner margin. 36—40 mm. Alaska, Canada, to the south as far as Colorado. — **abrasoides** Barnes & Benj. is less contrastingly marked than the nomenclatural form. The reniform macula is longer, the submarginal line narrower. The relations between *scripta* and *abrasoides* are similar to those between *rectangulata* and *arizonensis*. Described according to 1 ♀ from Arizona. — The larva is dark yellowish brown, often almost black, with a black dorsal line. Laterally yellow with black spots ending pointedly at the stigmata, sometimes with a few white spots there. Head yellow with dark brown spots. Cocoon feeble, deposited in moss.

rectangulata.*arizonensis*.

H. rectangulata Ottolengui is very similar to *scripta* (172 h) and *derasa*. The interior line is hardly angular at vein 1 in *derasa*, slightly angular in *scripta*, rectangular in *rectangulata*. The ground-colour is rather the same in all the three species, though somewhat darker in *rectangulata*. The marking which is white in *scripta* with a very slight pink tinge, is distinctly pink here. The submarginal line is broad and distinct in *derasa* and *scripta*, here it is narrow, dentate outside, faded inside. 35—40 mm. Atlantic States, Canada. — **arizonensis** Barnes exhibits a drab ground-colour on the forewing and thorax, not brown as in the type. The white blotch at the base of the wing is smaller. The pinkish white colouring at the middle of the costal margin and at the submarginal line is reduced. The colour of the hindwing corresponds with the forewing, thus grey not brown as in *rectangulata*. Described according to 1 ♂ from Arizona. BARNES & BENJAMIN ascertained in 1929 that *Habrosyne gloriosa* Gn. having been described from the Caucasus and never found again is identical with *rectangulata*.

chatfieldi Grote. This species or form reported from Alaska is merely referred to GROTE's List of North-American Eupterotidae in DYAR's List of N.-Amer. Lepid.; in GROTE's List, however, only the name *chatfieldii* [not *chatfieldi* as DYAR writes] is quoted without any further description.

2. Genus: **Thyatira** Hbn.

This genus has also been described already in Vol. II, p. 323. While the species of *Habrosyne* chiefly live in a cooler climate, the species of *Thyatira* are tropical for a great part in the Old World and predominantly so in the New World. Type: *batis* L. from Europe.

staphyla.

Th. staphyla Dgn. (172 i) is very similar to *batis* (Vol. II, pl. 49 c), but larger. The two white spots, mostly suffused with brown near the apex, are more oblong, their lower ends connected by one or several white streaks. The spot at the anal angle is rounded, with 2 smaller olive brown spots behind it at the margin. The basal spot is almost as in *batis*. A white streak between the two inner-marginal spots at vein 1, yellowish below it. On some specimens we notice a black, undulate, uniformly bent interior line, as well as a treble dark exterior line extending from the costal-marginal spot, touching the spot at the anal angle inside, excurved between. Hindwing brown in the distal half, lighter at the base. 34—38 mm. Bolivia, Peru, Colombia, Venezuela. — In a few specimens from Brazil I find the two spots at the costal margin to be rounder and not connected by a streak.

lama.

Th. lama Schs. is presumably similar to *staphyla*, but larger. Thorax dark brown, abdomen pale brown. Interior line of forewing as in *staphyla* (172 i). In the median area the costal margin and the cell dark brown, traversed by black lines. Interior line double, black, incurved above the inner margin. The median area below the cell is drab, narrowed by the exterior lines. A small yellow spot in the centre of the inner margin. Exterior line double, undulate, vertical to the costal margin, then excurved behind the cell, fine, dentate, slightly incurved to the inner margin. Behind it at the costal margin there is a large white spot with a small olive brown centre. From this spot another double dentate line extends filled with drab. Behind the cell, as far as vein 2, both the double lines are edged with white outside. A triangular blackish brown spot behind it at the costal margin, with a white dot. From the apex a broad white stripe, distally undulated, extends to vein 5, enclosing a faint olive brown streak. A large oval spot at the anal angle is edged with black outside, with white inside. It encloses an olive brown streak and pinkish flesh-coloured scales. Hindwing with a broad dark marginal area, with a light line inside, the basal area lighter. 45 mm. Described according to 1 ♀ from British Columbia.

mexicana.

Th. mexicana Edw. (172 i) was briefly described as a form of *batis* (Vol. II, pl. 49 e), but it is easily determined by its size. Somewhat darker than *batis* on both wings. The number and shape of the spots is not different, though they have a more extensive brown interior shadow. The specimens from STAUDINGER's collection, which I consider to be *mexicana* have a black interior line as in *staphyla* (172 i); from the spot at the costal margin a brown finely dentate line extends to vein 3, in light surroundings; from the exterior edge of

the spot mentioned another feebler dentate line extends; a submarginal row of dots from the apical spot. Hindwing with a light median band as in *batis*. The name *speciosa* Stgr. has been given to these specimens probably only i. l. 40—45 mm. Mexico, Bolivia, Panama.

Th. hersilia Drc. (172 i) slightly resembles *decorata* Mr. (Vol. X, pl. 85 a) from India. Forewing dark reddish brown with indistinct dark transverse lines and dingy white spots. One at the inner margin at the base, a parted one at $\frac{1}{3}$ of the costal margin, a small one at $\frac{2}{3}$ costal margin, an oblique double spot at the apex, a small one at the inner margin near the anal angle, and a larger spot obliquely above it. Hindwing dark brown, paler at the base. 48 mm. Described according to a single specimen from Guatemala.

Th. heurippa Drc. (172 h) is somewhat similar to the Eastern Asiatic *trimaculata* Brem. (Suppl. Vol. II, pl. 14 b, nec Vol. II, pl. 49 e). Ground-colour dark red-brown. A large round light olive brown spot at the base is edged with yellowish. An equally large spot beside it at the costal margin is edged with yellowish only in its anterior half, with numerous fine white dentate lines behind and below it. Hindwing lighter reddish brown. 38 mm. Panama, described according to a single specimen; the specimen figured is from Misantla, Mexico (Coll. DRAUDT).

? **Th. hypatia** Drc. (172 k). The author himself doubts whether it belongs to this genus. In fact, the scheme of markings is rather different, nothing is unfortunately said about the neururation. Forewing pale olive brown, spotted pinkish brown and whitish. A semicircular olive brown spot in the middle of the costal margin, a similar one at $\frac{1}{3}$ costal margin, a more round one near the apex. Smaller black spots at the base and below the first marginal spot. The central spot and the apical spot are edged with black inside. The darker brown spot at the inner margin is situate much farther towards the anal angle than in the other species. Marginal area with brown and greenish white spots. Hindwing pale olive brown, broadly darker at the margin. 36 mm. Panama. Only 1 specimen known.

? **Th. casta** Fldr. (172 i) may belong to this family, but it seems rather doubtful whether it belongs also to the genus *Thyatira*. Ground-colour pale olive brown with a dark brown marking. Two curved dark ante-median bands, broad at the costal margin, ending pointed in the submedian fold, small and larger radial spots before the interior band in the basal area. Median band broad at the costal margin, ending pointed in the middle of the wing. Before it at the inner margin as far as before the interior line there are 2 oblique semicircular rings filled with olive brown. Exterior line vertical to the costal margin as far as vein 4, slightly inserted behind the cell; bent inward between vein 4 and the inner margin. Darker brown behind it, except a pale, somewhat oblong spot at the apex, similar to the other species. Hindwing whitish olive, broadly brown at the margin. 46 mm. Bogota.

3. Genus: **Euthyatira** Smith.

Wings more elongated than in *Thyatira*. Base of palpi very hairy. Veins 3 and 4 of forewing slightly separated, 5 in the middle of the cross-vein, 6 a little below the upper angle, 7 + 8 and 9 + 10 stalked. Veins 3 and 4 of hindwing from the angle, 5 a little above it, 6 a little below the upper angle, 8 extends close beside it as far as the cell-end. Type: *pudens* Gn.

Eu. pudens Gn. (172 i). Thorax grey, abdomen brown. Forewing dark red-brown. A broad white band from the base of the costal margin to the middle of the lower cell-margin, where it ends broad. Behind it traces of a double interior line. A pinkish white double spot in the middle of the costal margin, two smaller ones behind it. From these spots 3 indistinct dentate white exterior lines proceed, more strongly incurved below the cell. An oblique white spot at the apex, its lower part filled with pale pinkish brown. An oval pinkish brown spot at the anal angle is edged with white. Hindwing ochreous, darker in the distal half, with an ochreous exterior and submarginal line. 40 mm. North Atlantic States. — **anticostiensis** Grote is greyer, the pink spots are less bright, the ground-colour is darker. From Anticosti (Gulf of St. Lawrence). — **pennsylvanica** Smith (172 k) is only a more extreme form of *anticostiensis*. It is without any pink at all, the maculae are more distinctly prominent, and the ground-colour is darker than in *pudens*. Pennsylvania. — The larva has a white head with 4 black spots. The body is whitish, somewhat diaphanous, with white dorsal spots, blackish at the segmental margins, stigmata pale brown, with few short light hairs. On *Cornus florida*.

Eu. lorata Grt. Forewing broader than in *pudens*, greyish brown, dusted white in the median area, the same around a deep brown triangular spot which forms the beginning of the submarginal line at the costal margin. Median lines distinct, black, nearing each other at the inner margin. Black spots behind the exterior line. Ring-macula small, round, near the erect oval reniform macula. A reddish, white-edged spot at the anal angle. A narrow undulate apical streak. The basal spot is angled in front, less extensive than in *pudens*. The apical spot of *pudens* is absent here. Hindwing yellowish brown with an undulating median shadow. Thorax light brown, laterally white. 40 mm. North Western States.

Eu. superba Barnes. Thorax light brown, abdomen yellowish brown. Forewing brownish, blackish at the costal margin, interior line black, indistinct, exterior line double, undulate, somewhat indistinct in front. The ring-macula is a small yellow indistinct spot. Reniform macula oval, erect, brown, edged lighter. Veins somewhat black, on both sides of the exterior line. The 5 large light spots are distinctly edged, more or

less encircled with white, filled with pink and yellowish brown shadows. The basal spot is the largest, extending to the exterior line which it joins inside. The upward prolongation is filled with pink and white, the lower one by a double yellowish spot. A brown quadrangular spot at the middle of the inner margin is edged with white above and outside. The spot at the anal angle is oval. Apical spot oval, filled with pink, edged somewhat white. The fifth spot at the costal margin near the apical spot is round, filled with yellowish brown, edged with pinkish white. Hindwing dark brown with a light median line. ♀ 40 mm. Arizona. Presumably only 1 specimen known.

tema. **Eu. tema** *Strecker*. Body brown, patagia greyish white. Forewing, base and apical spot greyish white. The basal spot is very angular and extends to the inner margin. A darker band behind it is traversed by dark brown lines. Median area paler, behind it follows a similar dark band with lines. Reniform macula indistinct. Marginal area paler grey. The pale apical spot is edged with dark outside. Hindwing light grey, darker at the margin. 42 mm. North-Western States. According to BARNES & McDUNNOUGH, *tema* is identical with the following species.

semicircularis. **Eu. semicircularis** *Grt.* is compared by the author with *Cym. improvisa* *Edw.* from which it differs in the absence of the yellowish green spots at the pink marking. Wings broad. Forewing with a creamy white, black-edged spot at the base, with a point in the submedian fold. A broad interior dark band behind it contains 3 or 4 black lines. Median area dark grey, the rest of the wing whitish grey. Behind the middle another indistinct dark band with 2 or 3 lines, nearing the first band at the inner margin. Ring-macula and reniform macula small, rather indistinct, close together. Submarginal line composed of black lunae, as in *lorata* where, however, it is not mentioned in the description. Hindwing yellowish grey, 40 mm. North-Western States. — *griseor*. **griseor** *Barnes*. Patagia dark, not light grey as in the nomenclatural form. Forewing slightly tinged with smoky grey, the lines more indistinct. The white basal spot and the apical spot are less prominent, especially indistinct is the former. Hindwing darker with a broad dark brown margin. 1 ♀, 40 mm. Nevada.

4. Genus: **Pseudothyatira** *Grt.*

Palpi thick, porrect. Forewing bent at the costal margin at the base, with a short dent of scales at the anal angle. Vein 5 from the middle of the cross-vein, 6 from the middle of the areole, 7 + 8 and 9 from its apex, 10 from its anterior edge. Veins 3 and 4 of hindwing slightly separated, 5 above the cell-angle, 6 from the upper angle, 7 a little back, 8 nearing 7 as far as behind the cell-end. Abdomen of ♂ laterally with a hair-pencil. Type: *cymatophoroides* *Gn.*

cymatophoroides. **Ps. cymatophoroides** *Gn.* (172 k). Thorax dark red-brown, abdomen lighter, with black tufts. Forewing still lighter. Interior line threefold, dentate, black. Rusty brown before it in the middle of the wing, black at the base. A rusty brown dot in the middle of the cell and at the lower cell-angle. Exterior line threefold, black, extra-angular below the costal margin, then almost extinct, obliquely inward. Submarginal line of black sagittal spots. A divided dark brown spot before it at the costal margin, a larger spot before it at the anal margin, edged with white inside. Hindwing reddish brown. 35—42 mm. Atlantic States, Nova Scotia as far as New Mexico.

expultrix. **Ps. expultrix** *Grt.* (172 k). Thorax and forewing red-brown, greyer in the marginal area. Interior line black, of a very irregular course, edged with white inside, two less distinct parallel lines behind it. The ring-macula is a rusty brown dot, the reniform macula narrow, black or rusty brown at its lower end, the rest finely edged with brown. An indistinct dark median line extends across the reniform macula. Exterior line black, double, rather indistinct, far outward close below the costal margin, then obliquely inward in large dents, the interior branch more distinct above the inner margin, edged with white. The black submarginal spots are intense. Anal angle rusty brown. Hindwing somewhat lighter than forewing. 38—42 mm. Canada to Texas.

5. Genus: **Cymatophora** *Tr.*

All the necessary details about this genus have already been given in Vol. II, p. 326, under the name of *Palimpsestis* *Hbn.* The 14 species of the latter are opposed by only 5 species in the American Fauna, 3 of which occur in North America. It is not sure whether the two South American species belong to this genus.

improvisa. **C. improvisa** *Edw.* is sometimes regarded to be identical with *Cym. tearlei* *H.-Edw.* (172 k); it is also very similar to *Euth. semicircularis*, but the interior black band is undulate in *improvisa* and incurved in the submedian fold, not uniformly bent. Moreover, the ring-macula is indicated in *improvisa*, the apical streak is not undulate, the basal spot extends to the inner margin. *improvisa* is also similar to the following *fasciata*, but the green basal area of *improvisa* is not so extensive as in *fasciata* and distinctly apple-green. In the marginal area only the apical spot and the submarginal line are green. The exterior line is much more oblique at the costal margin in *improvisa* than in *fasciata*. ? mm. North-Western States.

fasciata. **C. fasciata** *Barnes & McDunn.* Body brown, only the patagia grey. Forewing light violettish brown, with a slight whitish green at the base and at the distal margin, the broad median band of the same colour. The basal area is bordered by a curved line which is bent inward in the submedian fold, besides with 3 parallel dark lines before it. Median area with a small round black spot in the cell, a dark undulate median line behind it.

Exterior line double, almost vertical, slightly excurved behind the cell, incurved in the submedian fold, the interior branch deep black, the interspace filled with red-brown. Soon behind it a vertical pale green undulate line, then whitish green almost as far as the margin. Submarginal line finely black, beginning curved, continued as a greenish shadow with a dark edge to the anal angle, often absent. Hindwing dark greyish brown with a dark basal line and a light median band. 37 mm. Vancouver I.

C. tearlei *Edw.* (172 k) is sometimes considered to be identical with *improvisa*, but it is presumably a *tearlei*. distinct species. The original description is somewhat insufficient. It runs as follows: Ash-grey. The forewing is traversed by two undulate red-brown lines edged with black. The median area is somewhat lighter than the rest, the inner margin dark. Hindwing dark. It differs from *fasciata* in its dull grey colouring and less contrasting marking. The median area is insignificantly lighter and without any green colour. Our figure shows that also the shape of the exterior line is different, since it is not incurved at the costal margin and excurved only below the cell. Hindwing lighter than in *fasciata*. 40 mm. North-Western States.

C. moderata *Wkr.* Greyish brown. Forewing with greyish white rather straight transverse lines, in- *moderata*. distinct excepting the submarginal and neighbouring lines. An indistinct double row of black dots between them. Ring-macula and reniform macula large with incomplete greyish white edges. Hindwing dark brown. ♀ 35 mm. Bogota. Only this one specimen seems to be known.

C. temperans *Wkr.* Rusty yellow. Forewing with 4 light undulate lines, with white dots outside. The *temperans*. submarginal line is scarcely undulate. Ring-macula and reniform macula large, edged light. Black marginal lunae. Hindwing dark brown, lighter at the base. ♂ 34 mm. Rio de Janeiro.

6. Genus: **Polyploca** *Hbn.*

This genus has also been briefly, though sufficiently described already in Vol. II. p. 329.

P. oniroe *Dgn.* Wings narrow and long. Ground-colour grey, dusted with white at the costal margin. *oniroe*. pale yellow in the middle. Short black streaks at the costal margin. Ring-macula edged with pale yellow. No other distinct marking to be noticed. Hindwing semi-diaphanous, white, somewhat iridescent. 33 mm. Described according to a single excellently preserved ♂. Ecuador.

7. Genus: **Ausava** *Wkr.*

Palpi short. Antennae plain. short. Abdomen with feeble lateral tufts. Costal margin of forewing hardly bent. Only 1 species.

Au. triplaga *Wkr.* Greyish brown, metathorax darker. Forewing with indistinct undulate light trans- *triplaga*. verse lines. Three black spots at the costal margin with a white partition-line. A black streak behind the reniform macula and two others parallel to it, nearer to the distal margin. Hindwing with two undulate dark bands. ♂ 26 mm. Rio de Janeiro.

Psychidae Case-bearers.

As most of the peculiarities of this rare group of lepidoptera have been exhaustively treated in Vol. II (p. 369), Vol. X (p. 729) and Vol. XIV (p. 481) only a few remarkable traits will be dealt with here. The puzzling contradiction between the total immobility of the female imago and the world wide distribution of several of its species need only be mentioned as a number of explanations have been pointed out in the above named places. No other group of lepidoptera have so many chances of spreading as these where the larva when changing into a chrysalis adheres to every kind of object, posts, faggots, fruit, even to utensils in every day use; not infrequently in a waterproof case not subject to any outside influences. Branches of fruit rind falling into the water are much more easily swept or carried away than the pupae or imagines of large Rhopalocera, as for instance *Danaus archippus*, whose transportation from its (American) home to fairly remote regions such as Australia, New Zealand, Portugal, the Atlantic Islands, the Indian Archipelago (Jaluit etc.) has taken place under our very eyes so to speak. *Castniidae* and Central American *Syntomidae* have of late been repeatedly delivered alive to European Museums or bred from pupae which have been brought over. The invaders of the latter groups have not propagated, as introduction in sufficient numbers for copulation is hardly possible by this means. In the case of the *Psychidae* parthenogenesis takes place to a greater degree, as was pointed out in discussing the group in the volumes mentioned of the "Macrolepidoptera", so that the occasional drifting in of a single branch with a ♀ pupa clinging to it may lead to complete naturalization. The fact that such parthenogenesis has not yet been satisfactorily proved among the extremely similar forms of the *Oiceticinae* which are spread all over the southern hemisphere, does by no means exclude such a possibility, as just the *Psychidae* have revealed the amazing phenomenon that the same species is able to propagate in some districts entirely parthenogenetically, in others, however, constantly and in others again frequently sexually. It would therefore not be very surprising should this parthenogenesis come about in cases of artificial transportation also among species where, under normal conditions, it has never been observed, as it has been similarly observed among numerous insects of other orders as an adaptation to seasonal changes.

In addition to these qualities so favourable for conquering new patriae there are numerous others directed to the same effect. Just with certain *Oiceticinae* the eggs, even in regions without any real winter, often lie for weeks and months without releasing the little larvae, and it is not impossible that, as it frequently happens in the animal world, they await better conditions before emerging from their case. Moreover, we find an astonishing polyphagia among many *Oiceticinae*. Breedings of *Oik. geyeri* and *kirbyi platensis*, which I carried out in the Frankfurt Insect House proved the suitability of nearly all the foliage trees of the Zoological Gardens there as welcome food for the larvae, especially willows, plane-trees, Robiniae and many kinds of timber; only certain poisonous plants such as nerium and eucalyptus were disdained, and conifer needles were only slightly gnawed and then abandoned.

The temporary frugality of certain otherwise very greedy widely distributed *Psychidae* is also wonderful. While one is accustomed to find little power of resistance to hunger just among polyphagous sorts, the *Arctiidae* for instance, the *Oiketiscus* can do without any food for a very long time without showing any noticeable change in condition. Even the lack of fresh green food for a long time is not necessarily injurious, for if it once happens that all vegetable food fails, the larva which often accepts the driest leaves without distinction, stalks and all, even seeming to prefer them to fresh food at times, has another means of fighting starvation. When food is plentiful it cuts differently sized bits out of the leaves and fastens them outside on its case as if for decoration. Then, when food gets scarce, it rips these bits out of its case and devours them, no matter how dry they may be, patching up the holes produced in the bag with silk web.

I should like to take this opportunity of recalling an event (related in Vol. II, p. 353) when, in an absolutely treeless district, great fragments of branches of undoubtedly far distant trees were brought to me by a pampero (storm in the steppes). A cracking noise like distant rifle-fire sounded in the sky and showed me a wind-spout like a pillar, by which dry and fresh pieces of wood, some as thick as small logs, were whirled round and round and against each other, till they were broken into small pieces. On examining these later on I discovered small still inhabited case-bearer bags. This is noteworthy for the diffusibility of an insect species, as such wind-spouts may carry insects, which are unable to fly, hundreds of miles at great speed.

The further spread of colonies of *Psychidae* which have settled somewhere follows then most rapidly, for however incapable of locomotion the females are, the larvae are very nimble. A box full of collected *Oiketicus*-bags if left open will be deserted by its occupants in few minutes. They scatter in all directions into every nook and cranny of the room. They are seldom seen even on their feeding trees in the lazy quiescence which makes so many other larvae seem as if they had grown to the twig. On the contrary, I observed a continual bustle among the Australian *Oiketicus* on the Paramatta as well as among the South-American ones on the La Plata, clearly visible from the jerking of the cases they drag along.

For the reason already mentioned in Vol. X, p. 730, we do not wish to lay too much weight upon the fact that only 17 genera have been included here in the domain of the American *Psychidae*. As stated, there are just as many reasons for including further genera, *Acrolophus* for instance, as for omitting them in a work on "Macrolepidoptera". We have already mentioned the pros for the opinion that most *Psychidae* belong altogether to the Microlepidoptera and give preference here, as behoves a handbook, to what is of conventional importance.

For the sequence of the genera the Catalogue of DALLA TORRE was followed, just as in Voll. X and XIV. For the adjustment of the species in the genera more attention has been given to the views of the latest authors than to this catalogue.

a) Subfamily: **Chaliinae** *Hmps.* (*Oiketicoidinae Strd.*).

As the name *Chaliinae* was already used in the palaearctic part of the work (Vol. II, p. 364), we keep to it also here. The characteristic mark of the group is: the two inner-marginal veins of the forewing anastomose outwardly, no veinlet branching off towards the inner margin. Hind tibiae without spurs.

1. Genus: **Chalia** *Mr.*

Anterior tibia with a long spur. Antennae strongly pectinated, the pinnae gradually decreasing in length towards the tips. Forewing with stalked veins $4 + 5$ and $7 + 8 + 9$, hindwing without veins 5 and 8. In all the species treated here, however, the neuration differs from this rule.

künckeli.

Ch. künckeli *Heyl.* Veins $4 + 5$ and $8 + 9$ of forewing stalked, in the hindwing the veins 4—7 are short, 8 stronger in the middle and connected with the cell by a bar. Forewing yellow above; black are the base, the costal margin and the veins. On the short hindwing the apex projects hardly, the ground-colour is more rusty yellow. Under surface darker. The ♀ is ash-grey, the 3 first segments yellow. ♂ 24 mm. Argentina. — The larval bag is 35—42 mm long, cylindrical, longitudinally covered with grass. The single bits of grass are about 4 mm long, encircling the bag like a screw.

pizote.

Ch. pizote *Schs.* In the forewing of the ♂ veins $4 + 5$ and $8 + 9 + 10$ are stalked, 11 is absent, veins $4 + 5$ of the hindwing are shortly stalked. Antennae of the ♂ long and scantily pectinated, body and wings uniformly dark brown. ♂ 15 mm. Guatemala.

tristis.

Ch. tristis *Schs.* In the forewing veins 4 and 5 arise from the same base, 7 and $8 + 9$ from the upper cell-angle. In the hindwing veins 4 and 5 are close together, 8 distantly separated from 7. Ground-colour greyish brown. Wings densely scaled. ♂ 17 mm. Jalapa (Mexico).

zacualpania.

Ch. zacualpania *Dyar.* In the forewing veins 4 and 5 arise from the same base, $7 + 8 + 9$ are stalked. Hindwing with 7 veins, vein 8 connected with the cell by a bar. Wings grey, scantily scaled. 22 mm. Described according to a single specimen from Zacualpan (Mexico).

vigasi.

Ch. vigasi *Schs.* Similar to *zacualpania*, smaller, more transparent. Wings grey, semidiaphanous, scantily scaled with darker hairs. Costal margin of forewing finely black. Fringe darker grey. 16 mm. Las Vigas (Mexico).

rileyi.

Ch. rileyi *Heyl.* Antennae of ♂ of $\frac{1}{3}$ the length of the costal margin of the forewing, broadly pectinated in the middle, anterior tibia with a large spur. Wings greyish yellow, narrowly edged with brown, oblong, no

vein stalked. ♂ 12 mm. Missouri. — The larval bag is cylindrical, ash-grey, 11 mm long, covered with fine rests of bark or lichens. On the trunks of apple and pear trees. According to DYAR also on *Quercus marylandica*.

2. Genus: **Prochalia** *Barnes & Mc. Dunn.*

Antennae of ♂ bipectinate. Anterior tibiae with a long thorn. In the forewing all the veins are present, free, only 8 + 9 stalked, towards the inner margin no spur from the inner-marginal veins. Veins 4 and 5 of hindwing from the same base. Vein 8 not connected with the cell by a bar.

P. pygmaea *Barnes* (169 b). Body and wings uniformly blackish brown, similar to *Platoeceticus nigrita pygmaea*. (169 d). Abdomen as long as hindwing. 12½ mm. Described according to 1 ♂ from Florida. — The larval bag is narrow, cylindrical, 12 mm long, spun with pieces of lichens. Common on trunks of orange trees, but the breeding yielded only a single ♂.

3. Genus: **Dendropsyche** *Jones.*

Antennae of ♂ bipectinate to the tips. No spurs or thorns on the tibiae. Wings rounded. Forewing with 11 veins, 8 and 9 from the same base, the others separately, no spur to the inner margin. Hindwing with 7 veins all of which are separated, vein 8 sometimes with a bar to the cell.

D. burrowsi *Jones* is of a feeble structure. Uniformly smoke-brown, body hairy. 12 mm. Described *burrowsi*. according to 3 ♂♂ from British Guiana. — The bag is 12 mm long, conical, the largest width above 3—4 mm, below 1 mm. It is presumably carried by the larva in an erect not pendent way.

b) Subfamily **Psychinae** *H.-Schäff.*

The two inner-marginal veins of the forewing despatch a single spur to the inner margin. The hind tibiae are shorter than the anterior ones.

4. Genus: **Cochliotheca** *Rmb. (Apterona Mill.)*

The genus contains tiny lepidoptera of a frail structure with broad wings clothed with hair. Forewing typically with 10 veins, hindwing with 7. The larval back of the European species is curved like a snail-shell and clad with sand. Only 1 species in America.

C. fragilis *Barnes & McDunn.* (169 b). Forewing with all the 10 veins arising at equal distances, only *fragilis*. veins 4 and 5 a little nearer together. Hindwing with 7 veins, veins 4 and 5 from the same base or stalked. Vein 8 connected with the cell by a bar. Antennae of ♂ strongly pectinated, thorax thinly clad with long white hair. Wings blackish, semidiaphanous, long-haired. Abdomen short. 11 mm. 2 ♂♂ from Arizona.

5. Genus: **Psyche** *Schrk.*

All that is necessary has already been said about this genus in Vol. II, p. 361. Only one American species which, however, may also belong to *Platoeceticus*.

Ps. watsoni *Jones* (169 b). Similar, but larger than *Plat. gloveri Pack.* (169 c). Antennae of ♂ strongly *watsoni*. pectinated. Forewing with 12 veins, 4 + 5 and 8 + 9 stalked, sometimes also 7 + 8 + 9. The hindwing has 8 veins, 4 + 5 stalked or arising from the same base. Anterior tibiae without a thorn. Antennae black, wings brownish black, body delicate, little or not projecting beyond the hindwing. 15—20 mm. Haiti. — Larval bag 15—20 mm long, strongest in the middle, composed of grey silk, irregularly spun with small pieces of leaves and bark.

Ps. bergi and *Ps. burmeisteri Weyenbg.* are quite irrecoznizably described and figured, for which reason they have been passed over here.

6. Genus: **Eurycyttarus** *Hmps.*

In the forewing of the type veins 7 and 8 + 9 arise from the upper cell-angle, vein 6 is absent in both wings.

E. confederata *Grt. & Rob.* (169 b). Veins 8 + 9 of forewing on a very long stalk. The bar from vein *confederata*. 8 to the cell on the hindwing is situate nearer to the cell than in the other species. Blackish brown, wings not diaphanous, broad. 15—20 mm. In the Southern States and as far as New York. — The bag is 15 mm long, longitudinally covered with projecting needle leaves.

E. tracyi *Jones* (169 b). The antennae are larger and more broadly pectinated than in *confederata*, each *tracyi*. dent of the comb with a fine tuft at the tip. Body hairy, especially densely so on the thorax. Wings broad, forewing short, so much rounded that an apex or anal angle is not discernible. Veins 8 and 9 not or very shortly stalked. In the normally round hindwing the bar extends from vein 8 to the middle of the cell. Ground-colour

brownish grey, thorax and forewing somewhat darker than the hindwing and abdomen, slightly diaphanous, with a violettish blue gloss above and beneath. ♂ 17—19 mm. Mississippi. — Larval bag 20—27 mm long, cylindrical, outside with closely appressed pieces of dry grass. As the imago has a smaller expanse than in *confederata*, but a stronger structure, the bag is relatively large.

cacoenemis.

E. cacoenemis Jones (169 b) is closely allied with *tracyi*, but the legs are remarkably weaker. According to the author, this depends on the shape of the ♀ larval bag which is not so broad at the end as in *tracyi*. The rounded apex on the forewing projects a little farther than in *tracyi*, veins 8 + 9 are stalked. Vein 8 of the hindwing is fused with the middle of the cell for some distance, which may also occur in *celibata* (169 c). Antennae as in *tracyi* (169 b). Ground-colour blacker, less brown. Forewing with traces of a black streak at the cross-vein. Laterally projecting hair at the end of the abdomen. ♂ 17 mm. Described according to 5 bred specimens from Florida. — The larval bag is 25—30 mm long, similar to that of *tracyi*, but less uniformly covered with small pieces of bark, which are often absent at the end. Similar bags have been found by JONES also in Carolina.

edwardsi.

carbonaria.

E. edwardsi Heyl. (= *carbonaria* Pack.) (169 b). According to JONES, *edwardsi* and *carbonaria* are identical, and *edwardsi* is not a synonym to *gloveri* as DYAR presumed. — **carbonaria** (169 c) was described in 1887 according to two specimens from Texas and was no more found, until JONES, in 1932, visited a district in Texas of a similar nature though of an easier access than the typical one, where he discovered ample material of larval bags in the first half hour. In the forewing veins 7 and 8 + 9 arise normally together, 8 + 9 being shortly stalked, but they may also be separated. Veins 4 and 5 may arise in both wings from the same base or they may be stalked. In the hindwing a bar extends from vein 8 to the middle of the cell-margin. Body black, long-haired, rather strong. Wings broad, rounded, blackish, somewhat diaphanous. 20—22 mm. Texas. The ♀ is 12 mm long, yellowish white, the thorax above olive brown. — The larval bag is 22—26 mm long, cylindrical, 4 mm strong, silky, wood-coloured brown, smooth. According to the figures, the tone of colours of *edwardsi* and *carbonaria* is somewhat different.

celibata.

E. celibata Jones (169 c). All the veins of the forewing arise at about equal distances except veins 7 and 8 + 9. The neuration of the hindwing is very variable in the ten lepidoptera that were examined; vein 8 is mostly fused with the middle of the cell, and veins 4 and 5 may be distantly separated or also shortly stalked. The tiny lepidopteron is brownish black, with broad and round wings, a few white hairs on the body. Abdomen as long as the hindwing. Wings with moderately dense scales, the costal margin of the forewing narrowly darker. 10—12 mm. Florida. — The larval bag is about 15 mm long, cylindrical, longitudinally irregularly covered with fine needle-leaves and pieces of grass.

polingi.

E. polingi Barnes & Benj. (169 c). Antennae strongly pectinated. In the neuration very similar to the European *Can. unicolor* Hfn. (Vol. II, pl. 55 a). In the hindwing the position of veins 4 and 5 varies a little. Vein 8 is connected with the cell by a bar. Similar to *edwardsi* (169 b), but the thorax is whitish, the abdomen with black hair. Wings with a slight bronze reflection, somewhat diaphanous in the distal area, the fringe white. Apex of forewing more pointed, the distal margin more oblique, straighter than in *edwardsi*. 19—21 mm. Numerous ♂♂ from Arizona. — The bag is 34 mm long, 10—12 mm strong at 1/3 from the upper end, pointed at the other end, of a pale grey silk, looking as if it were densely covered with shield-lice.

7. Genus: **Pachythelia** Ww.

Forewing with 11 veins, hindwing with 7 veins, in both cases without vein 6. Antennae short, but pectinated to the tips. Anterior tibiae with a long thorn. The genus contains only 1 European species (*villo-sella* O.) and 1 American species.

lepidopteris.

P. lepidopteris Dyar. Antennae of ♂ long pectinated. Forewing with 12 veins, hindwing with 8, thus against the rule. Veins 6 + 7 of forewing stalked and 9 + 10 shortly stalked, 2—5 well separated. All the veins of the hindwing arising separately, 8 connected with the cell by a bar in the middle. Wings broad, rounded, thinly scaled black. 17 mm. Described according to 2 ♂♂ from Colima (Mexico). — The other *Pachythelia*-species described by DYAR has been transferred to *Hyaloscotis* by JONES; to which genus *lepidopteris* belongs in fact, seems to be not yet ascertained.

8. Genus: **Acousmaticus** Btlr.

Antennae almost as long as the forewings, very strongly pectinated. Neuration not described. Both wings oblong. Costal margin of forewing straight.

magnicornis.

A. magnicornis Btlr. (169 c). Body and forewing greyish brown, the veins brown, lighter at the cross-vein with 2 black dots. Hindwing whitish. ♂ 22 mm. Chile. Presumably no specimen known besides the type. Judging from the exterior, the species scarcely belongs to the *Psychidae*.

9. Genus: **Thanatopsyche** Btlr.

In the contours similar to *Thyridopteryx*. Veins 4 + 5 and 8 + 9 of forewing stalked. The two inner-marginal veins do not send a spur to the inner margin (as in the *Chaliinae*), except in *apicalis* Hmps.

T. chilensis Philippi (169 c) is the oldest American species described from this family. Antennae strongly *chilensis*. pectinated, these as well as the body and legs jet-black, long-haired. Wings almost quite hyaline, only the veins deep-black. ♂ 30 mm. Chile. — The larval bag is about 62 mm long, 18 mm thick, strongest at $\frac{1}{3}$ of its length, parchment-like. On fruit-trees, roses, arbor vitae. The larva seems to feed on the young bark.

Th. canescens Btlr. (169 d) is similar to *chilensis*, but smaller. Thorax thinly covered with grey hair. *canescens*. Abdomen blackish; wings grey, diaphanous, veins and margins black. 22 mm. Chile. Larval bag very similar to that of *chilensis*.

Th. thoracica Schs. Veins 4 and 5 arise separately on both wings. Thorax and base of abdomen brownish *thoracica*. ochreous, the rest greyish black. Wings brownish black. The cell of the hindwing is somewhat diaphanous 46 mm. Described according to 1 ♂ from British Guiana.

Th. apicalis Hmps. Body black, patagia with large white spots. Wings hyaline with a few black hairs, *apicalis*. the veins and margins black. Costal margin of forewing broader black in its exterior half. The inner-marginal area of the hindwing is black. ♂ 22 mm. Bahama Is. Three specimens are known.

(Genus: **Psychonoctua** Grt.)

By this generic name the species *personalis* Grt. has been described as a *Psychida*. But as the two other species *terrafirma* Schs. and *poam* Dyar were placed to the *Cossidae* by their authors, we shall also deal with the genus there. In the catalogue of DALLA TORRE they are probably wrongly mentioned as *Psychidae*.

10. Genus: **Thyridopteryx** Steph.

Body strong, densely haired. Antennae short, strongly pectinated, with bare tips. Abdomen markedly projecting beyond the round hindwing. Wings hyaline. All the 12 veins of the forewing are present, veins 3 and 4 nearer together. 7 + 8 stalked. Veins 2—5 of hindwing equally separated. 6 absent, 7 and 8 more or less anastomosing.

Th. ephemeræformis Haw. (= *coniferarum* Pack., *plumifera* Steph.) (169 c). Though the neuration is *ephemerae-* of course normal in a great number of specimens of this common species, yet the variability is enormous. *formis*. According to JONES, the number of veins on the forewing may vary between 14 and 9, on the hindwing between 8 and 5. Accordingly, the arrangement of the *Psychidae* by their neuration may be believed to be almost impossible, if one considers that a similar variability might also occur in other species, if a sufficient number of specimens were available. Besides, however, some specimens of *ephemeraeformis* also show cross-bars and accessory cells — one might almost say in impossible places — so that one is reminded of quite different groups of insects. The confused schemes of veins published by WEYHENBERGH *) for his species are even surpassed here. Antennae dark brown, body brownish black, wings hyaline. Costal margin of forewing narrowly blackish in its exterior part. Hindwing narrowly blackish at the costal margin, broader at the inner margin, the veins brown. ♂ 26 mm. New York to Florida, Bahama Is. — The bag of the ♂ is 35—45 mm long and 6 mm thick in the middle, besides the clothing with small pieces of wild cherry, willow, oak, conifers; the larva may even live on herbs. According to the plant on which the larva lives, the bags look rather different. Those of the ♀♀ are about 60 mm long, 15 mm thick. The ♀ does not leave the larval bag. As soon as the pupal case has burst, ♂♂ are allured, the abdomens of which are enormously stretched during the copulation. The only thing that is not variable in *ephemeraeformis*, is the appearance of the imago towards the end of summer and the hibernation of the eggs.

Th. vernalis Jones (169 d) resembles the preceding species, but it differs in the time when it flies. *vernalis*. The larva hibernates, the imago appears in spring. In 2 of 5 specimens veins 4 + 5 of the hindwing are stalked, and veins 7 and 8 of the hindwing anastomose more or less. The hindwing is thereby more rounded than in *ephemeraeformis*. The collar is remarkably grey, and the tegulae are also somewhat mixed with grey. Otherwise the imago seems not to differ. 25 mm. Delaware to Georgia. — The larval bag is 38—50 mm long, 8 to 11 mm thick, rather cylindrical, fastened to bark, spun outside with rests of bark and lichens, not with pieces of leaves. The shape of the bag is not covered by the small size of these parts as it is mostly the case in *ephemeraeformis*. It lives on *Pinus rigida* and presumably also on other species of *Pinus*.

Th. meadii H.-Edw. Wings hyaline, without black scales at the inner margin of the hindwing. Veins *meadii*. pale orange. ♂ 25 mm. Mohave Desert (California). — The bag is smaller than in *ephemeraeformis*, cylindrical.

* In Tijdschr. v. Ent. 27, t. 2, f. 7—9.

Th. alcora Barnes. The description corresponds exactly with that of *ephemeraeformis*. The only difference is that nothing is said about the colour of the veins. The size (25 mm) is also similar. Described according to 1 ♂ from Arizona.

pallidore-nata. **Th. pallidovenata** Grossbeck resembles a large *ephemeraeformis*. Antennae brown, yellowish at the tips. Body above and beneath dark smoky brown, with a silky gloss. Wings whiter hyaline than in *ephemeraeformis*, the veins also paler. Forewing narrowly dark brown at the costal margin, broader so at the inner margin at the base. Hindwing the same at the two margins. ♂ 34 mm. Described according to a single specimen from Florida. The author thinks that the Florida specimens of *ephemeraeformis* mentioned in literature belong to *pallidovenata*.

thoracicum. **Th. thoracicum** Grt. is smaller than *ephemeraeformis*, wings scantily scaled. Thorax with pale silky hair, the other hair brownish black. Forewing with a distinct partition-vein in the cell, which is absent in *ephemeraeformis*. ♂ 25 mm. Described according to 2 ♂♂ from Cuba.

microptera. **Th. microptera** Schs. has only 9 veins in the forewing, 3 in the hindwing. Body black, only the metathorax and the abdomen at the base brownish ochreous. Wings hyaline. Forewing with brownish ochreous veins in the basal area. The hindwing has long black hairs except at the costal margin. ♂ 23 mm. Cayenne. Described according to a single specimen.

seitzi. **Th. seitzi** sp. n. (169 e) is the smallest species. The veins 2 to 5 of the forewing follow each other at about equal distances, 6 is absent, 7 and 8 from the upper cell-angle, 10 a little farther back, 11 present. In the narrow hindwing a vein extends from the very broad and long cell into the apex, one more each above and below it at equal distances to the margin. Above it the cell bends outward almost as far as the costal margin and despatches a short vein from the anterior bend to the margin. Body black. Antennae dark brown. Forewing hyaline. Brown scales at the inner margin at the base and at the costal margin at the interior half. The exterior part at the costal margin and the distal margin are quite narrowly black. Hindwing narrow, the terminal third black, the costal margin narrowly black, the inner margin with white hairs. ♂ 16 mm. Rio de Janeiro. taken by Dr. SEITZ. Type in the Senckenberg Museum.

(Genus: **Dipyle** Guer.)

The author assures that *Dipyle* is allied to the genus *Oiketicus*. The cocoon is twice as long as it is thick and is open on both sides. The shape resembles that of a Venetian gondole. All this shows that the author had a *Pecrophorida* at hand. The species *boucardi* Guer. has thus been wrongly ranged in DALLA TORRE's Catalogue.

11. Genus: **Animula** H.-Schäff.

Antennae of ♂ bipectinated to the tips, in contrast with the likewise hyaline species of *Thyridopteryx*. Veins 8 + 9 of forewing stalked, 5 absent. In the hindwing 4 veins are present, besides vein 8 which anastomoses with the cell. Two species are known in the Indo-Australian Region, among them the typical one (*herichi*), from South America there are 3, and two more from unknown habitats.

dichroa. **A. dichroa** H.-Schäff. (169 d). Antennae blackish. Body densely covered with black hair. Forewing hyaline, the veins pale yellow especially at the costal margin. On the hindwing only the cell is hyaline, faint black dusting behind it, the inner margin broadly covered with greyish black hair. 28—32 mm. Colombia, Venezuela. 1 ♀ which might belong to it is 26 mm long, 5½ mm thick, yellowish brown, with densely arranged red-brown spots, a dark brown head and a blackish neck-shield.

limpia. **A. limpia** Dgn. resembles *dichroa* (169 d). Antennae black, body with long black hair. Forewing hyaline, the costal margin and the veins at the base yellow, then gradually covered with black scales, a few black scales also on the whole wing. They are absent in *dichroa*. The hindwing is black only at the inner margin, thus less extensively black than in *dichroa*. 23—28 mm. Described according to 5 specimens from Ecuador.

basinigra. **A. basinigra** Fldr. (169 d). The figure shows a species which is less similar to *dichroa* than to *dimidiata*. Body dark brown. Both wings hyaline, somewhat yellowish, the interior two fifths of both wings dark brown according to the figure, not black as the name indicates. ♂ 18 mm. Brazil. No further specimens seem to have been found later on.

Origin of the two following species unknown.

dimidiata. **A. dimidiata** Heyl. The shafts of the short antennae greyish yellow, with dark brown pectinations. Body with long gray hair, scarcely projecting beyond the hindwing. Wings hyaline. The forewing widens outwardly. The base densely covered with blackish brown scales, the margins narrowly black, the fringe with yellowish tips. Hindwing rounded, the base, margin and fringe as in the forewing. ♂ 22 mm. — The larval bag is 60 mm long, strongest near the base, longitudinally irregularly covered with rests of dry leaves of different sizes. Described from the Coll. OBERTHÜR, but apparently not figured.

basalis. **A. basalis** Heyl. Antennae short, yellow, with long blackish brown pectinations. Body with whitish hair. Forewing almost quite hyaline, only the base of all the cells densely covered with blackish hair. Hind

wing quite hyaline, almost circular, with long whitish hair at the inner margin. ♂ 24 mm. Described from the Coll. STAUDINGER where, however, it is no more present.

Subfamily: **Oeceticinae** *H.-Schäff.*

In the forewing the two inner-marginal veins anastomose and send several branches to the inner margin. The partition vein of both cells is forked.

12. Genus: **Clania** *Wkr.* (Eumeta *Wkr.*, Cryphothelea *Wkr.*)

Antennae of ♂ pectinated to the tips. Hindwing somewhat shorter than in *Oiketicus*. Forewing with stalked veins 4 + 5 and 8 + 9, all the veins present. Vein 8 of the round hindwing mostly sends spurs to the costal margin. Anterior tibiae with a long thorn. In Vol. X we enumerated 21 species from the Indo-Australian Fauna, in the American Fauna there are but 2 species.

C. surinamensis *Mschlr.* The species is described as a *Psyche* and compared by the author with *unicolor surinamensis*. *Hfn.* (Vol. II, pl. 55 a), while HEYLAERTS has placed it to the genus *Clania*. Antennae blackish brown, the body somewhat lighter, corresponding with *unicolor*. Forewing with a straight distal margin and a sharper apex than in *vilosellae*. The colour of the wings is the same as in *unicolor*. 23 mm. 1 ♂ known from Paramaribo.

C. brasiliensis *Heyl.* Similar to *surinamensis*. Antennae dark brown, with long pectinations up to the tips. Body and wings blackish brown, densely scaled. Forewing slightly bent at the costal margin. Hindwing slightly inserted at the distal margin. ♂ 23 mm. Brazil. — The bag is about 24 mm long, densely covered with pieces of light lichens and darker leaves. The larva is blackish, with yellow dots and streaks, the 3 anterior segments yellow.

13. Genus: **Platoeceticus** *Pack.*

Small species. wings broad. vein 6 present in both wings.

Pl. gloveri *Pack.* (169 c). ♂ uniformly dark brown, the ♀ is oval, whitish. — Larval bag 14—18 mm long, *gloveri*. strongest (5 mm) in the middle. The larva lives on orange trees. ♂ 18 mm. Florida.

Pl. costaricensis *Schs.* Body and wings dark greyish brown. Forewing browner in the interior two thirds, the veins very dark, veins 4 + 5 on a long stalk. Veins 4 + 5 of hindwing on a short stalk. 34 mm. 1 ♂ known from Juan Vinas (Costa Rica).

Pl. aphaidropa *Dyar.* Neuration as in *costaricensis*, but also veins 9 + 10 of the forewing stalked. Forewing triangular, hindwing rounded, brown, thinly scaled, with a faint bronze gloss. Forewing with darker veins, the apex and distal margin somewhat more bronze. 1 ♂, 19 mm, from Panama.

Pl. symmicta *Dyar.* Forewing broad with a round apex, hindwing rounded triangular. Ground-colour brown, somewhat lighter on the hindwing. Forewing: veins 8 + 9 stalked, 10 free. On both wings veins 4 and 5 arise from the same base. 12 mm. Panama.

Pl. marona *Schs.* Body and wings brownish black. Veins 4 + 5 stalked only in the forewing. 26 mm. 1 ♂ known from Cayenne.

Pl. rebeli *Köhler* (169 d). Described as *Chalia*, later on placed here by the author. Similar to *Ch. künckeli*, but the shape of the bag is different. Imago blackish brown. The original figure shows a strongly built insect with rounded wings. The distal third of the forewing seems to be lighter, both wings with small light round spots (? damaged). — The bag is 15—25 mm long, quadrangular, irregularly covered with transverse thorns. 5 mm thick, on *Cynara cardunculus*.

Pl. macleayi *Guild.* (169 d). Described as *Oiketicus* and compared with *Oi. kirbyi* which has quite different contours of the wings and is not in the least similar. Body delicate, abdomen just as long as the hindwing. Wings broad, rounded, dark brown. 18 mm. West Indies. — The larval bag is 20 mm long, 5 mm strong, conical, covered with projecting little pieces of lichens. We reproduce the original figure of the lepidopteron though it is hardly complete.

The two following species were described as *Manatha* *Mr.*, but later on placed here by their authors.

Pl. nigrita *Barnes & McDunn.* (169 d). Veins 4 and 5 of the forewing may be stalked, but it is rarely so; 8 + 9, however, are stalked, sometimes also 7 + 8 + 9. Veins 4 + 5 of the hindwing sometimes stalked. A bar from vein 8 to the cell seems to be absent. Size and colouring of the imago similar to that of *Eur. edwardsii* (169 b), but of a somewhat duller black, separated by the neuration. ♂ 16—18 mm. — The larval bag resembles that of *confederata*, it is interwoven with fine particles of grass and outside longitudinally covered with short caulicles of grass. Described according to 7 ♂♂ from Florida and Texas. According to DYAR, the imagines of *nigrita* and *gloveri* are not discernible.

jonesi. **Pl. jonesi** Barnes & Benj. is similar to *nigrita* (169 d), but smaller, with shorter antennal pectinations. In *jonesi*, veins 4 + 5 of the forewing are not stalked as a rule. Separated from *nigrita* by the antennae and the genitals. Described according to 20 ♂♂ from Texas. — On the occasion of this description another species is mentioned, which may be identical with *jonesi* or *gloveri* of which no more material is preserved in the collections. 20 ♂ bags yielded lepidoptera which had the same antennae as *jonesi*, but black wings as in *confederata*, without the brown tints of *jonesi* and *nigrita*. The larvae fed on blossoms and delicate leaves of *Crataegus*, but neither on leaves of fruit-trees nor on grass. The bags resemble those of *gloveri*, they are therefore only spun over with very fine particles of plants, not with large pieces.

Of the following three species only the larval bags are known.

tandilensis. **Pl. tandilensis** Köhler. The bag is 18—22 mm long, covered almost in parallel order with grass-pieces of different lengths, some of them being longer than the bag. Diameter 3—4 mm. The larva lives on Gramineae, but the adult larva may also feed on the blossoms of the Malvacea *Pavonia cymbalaria*. Argentina.

rugosus. **Pl. rugosus** Köhler was described from the same district. The bag is just as long, but thicker, spun over with obliquely arranged parallel remnants of herbs, not of grasses, though it feeds on grass.

14. Genus: **Oiketicus** Guild.

While the genus is represented only by 2 species in the Indo-Australian Fauna, the American Fauna contains 12, some of which occur in the Southern States; of 3 species only the bag is known. In the oblong forewing veins 4 + 5 and 7 + 8 + 9 are stalked, a few spurs extend from the inner marginal vein to the inner margin. Hindwing almost triangular. Anterior tibiae with a long thorn.

Of the first three species only the bag is known.

westwoodi. **Oi. westwoodi** Berg. The bag is about 90 mm long, 25 mm thick, conical, spun over with few particles of plants, similar to that of *geyeri*. According to KOEHLER, the size is 60 and 18 mm. The larva is similar to that of *kirbyi* but discernible by white dots on the dorsum of the segments 4 to 6, which are hardly noticeable in *kirbyi*. The rest of the body is similarly coloured, only the head is redder. The antennae and parts of the mouth being white in *kirbyi* are red here. Body with more numerous and more distinct black lateral dots than in *kirbyi*. On species of *Piptadenia*. Argentina.

elegans. **Oi. elegans** Köhler. The bag is 22—28 mm long, grey, 4 mm thick, somewhat narrower towards the end. Not spun over with particles of plants. On tree-like Leguminosae. The case seems to be very small for a species of *Oiketicus*. Described from Argentina.

davidsoni. **Oi. davidsoni** H. Edw. According to DYAR, the species surely belongs to some other genus, since the bag is longitudinally covered with branchlets which are partly longer than the bag. Length of bag: 40 mm.

geyeri. **Oi. geyeri** Berg (= *tabacillus* Weyenbgh.) (169 e). Widely distributed, but much rarer than *kirbyi*. Antennae blackish. Forewing reddish brown, body more yellowish, hindwing lighter, somewhat diaphanous. Forewing without any marking, but the bar of the two inner-marginal veins seems to be somewhat lighter. Corresponding to this scheme of markings, which is quite different from that in *kirbyi*, the larval bag is also different, up to 60 mm long, 12 mm thick at its upper end, then slowly getting narrower, 4 mm thick at the end, quite smooth, looking at the end as if it were torn. According to KOEHLER's statement, the ♂ does not emerge at this end, but the larva makes an opening for emerging about $\frac{1}{3}$ distant from the end. BERG states the bag to be 80—120 mm long, which seems to be rather much. On species of *Acacia*. The imago, 36—48 mm large, is known from Venezuela, Uruguay, Argentina. — A very dark specimen which, however, presumably does not belong to *specter* is before me from Blumenau from the Senckenberg Museum.

specter. **Oi. specter** Schs. forms a transition to *kirbyi* and the allied species. Body dark greyish brown, wings the same, scantily scaled. Forewing with a paler grey cross-vein, the space in and behind the cell darker grey, the same at the base at the inner margin. Hindwing dark grey at the inner margin. ♂ 50 mm. Venezuela.

kirbyi. **Oi. kirbyi** Guild. (= *fugurator* H.-Schäffl., *gigantea* Z.) (169 e). Antennae blackish. Body and wings dark red-brown. The cell of the forewing is very dark, also the space behind it as far as the bifurcation of veins 8 + 9 and downward as far as the upper inner-marginal vein. Cross-vein white with feeble outward dents. In the copulation the abdomen of the ♂ is stretched to 2 or 3 times its length. 38—45 mm. Central America

platensis. to Brazil, also in Cuba. — **platensis** Berg (169 e) is somewhat smaller and of a much lighter ground-colour, but the dark places almost just as dark as in *kirbyi*, thus more contrastingly marked. 35—38 mm. Argentina,

mexicanus. Uruguay. — **mexicanus** Heyl. (169 f). I have not seen the description of this form, but only the type in the Berlin Museum. It is allied to *platensis* by the ground-colour being almost just as light, but it differs in the shape of the hindwing which is straight at the distal margin in *kirbyi*, well rounded in *platensis*, distinctly inserted in *mexicanus* as well as in *poeyi*. — **poeyi** Lucas (169 e) is somewhat more slender, still darker than *kirbyi*, the margin of the hindwing is strongly inserted. 36—42 mm. Cuba, Portorico, also from Blumenau. — The bag differs from the smooth conical shape of *westwoodi* and *geyeri*, it is 45—50 mm long, strongest at $\frac{1}{3}$ of its length,

about 15 mm, more pointed towards the end, covered with protuberances. The larva of the form *platensis* is doing much harm in Argentina. It feeds on all the home and imported foliage trees, also on fruit-trees. Only conifers and Eucalyptus are spared.

Oi. abboti Grt. ♂ sand-brown with a hyaline stripe at the cell-end of the forewing, narrowly paler at *abboti*. the distal margin. A blackish streak at the base of vein 1, being absent in *kirbyi* and its forms, and a broad shadow from the cell-end to the distal margin. ♂ 30 mm. Florida. — The bag is about 35 mm long, densely spun with transversal leaf-stalks.

Oi. townsendi Towns. The cell in the forewing "solidly" blackish brown, also without the light cross-vein blackish brown. Veins 8 + 9 stalked, also veins 4 + 5 stalked in most of the specimens. — **bonniwelli** *bonniwelli*. Barnes & Benj., described as a species, is a form of *townsendi* according to JONES. Ground-colour more smoke brown, the marking less distinct. *townsendi* is said to have a pale streak at the anterior edge of the cell on the forewing. According to JONES, both the forms differ little from *abboti*. According to BARNES and BENJAMIN, the body and wings are yellowish brown. Forewing with a black patch at the base of vein 1. The cell is black, more faded behind it, the cross-vein intensely white. Similar to *abboti*, but larger, lighter, the hindwing rounder. 42 mm. From New Mexico, Texas. The cases of both forms are not different; the temperature and other influences decide which form emerges. — The bags are longer than in *abboti*, longitudinally covered with leaves and leaf-stalks.

Oi. dendrocomus Jones (169 e) is the largest species, similar to *townsendi*. The forewing shows veins *dendrocomus*. 8 + 9 stalked, but 4 and 5 mostly not stalked, thus contrary to *townsendi*. Veins 4 and 5 of the hindwing are mostly neither stalked. Only the lower part of the cell on the forewing is intensely blackish brown, not the whole cell. The shadow behind the cross-vein is very short, so that the marginal area is not interrupted by it. Nothing is mentioned about the ground-colour of both wings; it will be similar to that of *townsendi*. 45 to 48 mm. Arizona. The ♀ is 46 mm long, 10 mm strong, dull yellowish white, the head and the thoracal dorsum darker yellow. — The larval bag is enormous, 80—130 mm long, clad with long leaf-stalks, and thereby about 20 mm thick. The bags of the ♂♂ are without these stalks in the lower thirds. On Robinia, Platanus, Tamarix.

Oi. basiger Wkr. The species was described in 1866, since when no more specimen seems to have been *basiger*. found. Body rusty brown. Forewing spotted brown, with black dots at the costal and interior margins. A black spot near the base, next to it a triangular silvery spot and a few silvery dots above the inner margin. The shape of the wings and the long abdomen are mentioned in the description, but owing to the silvery spots it is somewhat doubtful whether the species belongs to the *Psychidae*. 58 mm. Bogota.

The two following species have not completely scaled wings. In *orizavae* the margin is semidiaphanous, in *toumey* both wings are almost quite hyaline.

Oi. orizavae Schs. Forewing smoke grey, almost black at the inner margin, the exterior half of the *orizavae*. cell likewise almost black. A white spot at the cross-vein as in *kirbyi*, but less notched. Distal margin semidiaphanous. Hindwing smoky grey, broadly blackish at the inner margin. The distal margin from vein 2 to the apex semidiaphanous. ♂ 39 mm. Orizaba (Mexico).

Oi. toumey Jones (169 f) is very similar to *Thyr. ephemeraeformis*. Antennae brown, broadly pec- *toumey*. tinated, tips bare. Anterior tibiae with a fine tibial leaf, half the length of the tibia itself. Abdomen long and delicate, projecting far beyond the hindwing. Veins 4 + 5 stalked in both wings, veins 8 + 9 also short-stalked on the forewing. Wings hyaline, the veins yellowish brown, only the inner margin with brown hair, the costal margin of the hindwing with dark scales. 28—32 mm. Tucson (Arizona). — The bags very common on Acacia, 55—60 mm long, exceptionally to 100 mm and 10—12 mm thick on two fifths of their length, then growing thinner, greyish white, irregularly spun with pieces of leaves and stalks.

15. Genus: **Hyaloscotus** Btlr.

Wings broad, vein 6 absent in both wings, by which it is distinguished from *Platoeketicus*. Inner-marginal vein of forewing with a spur to the inner margin. *fumosa* exhibits a long thin thorn on the anterior tibiae, which is not yet ascertained in *pithopoera*.

H. fumosa Btlr. (= *fragmentella* H. Edw., *coniferella* H. Edw.) (169 f). This synonymy is probably *fumosa*. correct according to JONES, but it must yet be ascertained. The name *fragmentella* is prior to *fumosa*. The forewing of *fumosa* shows veins 8 + 9 short-stalked, but 4 and 5 are mostly not stalked. The species is delicately built, originally described as a Lithosiid. Wings rounded, scantily scaled, more densely scaled only at the veins and margins. Body blackish with long white hair. Wings smoky grey, the forewing somewhat darker than the hindwing. 26—28 mm. California. 5 ♂♂ were found by Lord WALSINGHAM. 50 years ago, they are the only specimens known to this day. — The bags are 20—25 mm long, 5 mm thick, longitudinally covered with fine remnants of plants.

H. pithopoera Dyar. Wings scantily scaled, grey, without any marking. 20 mm. From Idaho. Blue *pithopoera*. Mountains (Wash.). — The bag is longitudinally spun with small pieces of grass. Size not mentioned.

16. Genus: **Zamopsyche** Dyar.

Body delicate, wings oblong. Forewing with 11 veins, 8 + 9 stalked, the other veins free. Hindwing with veins 4 and 5 from the same place, all the veins present. Vein 8 connected with the cell by a feeble bar.

commentella.

Z. commentella Dyar. Wings diaphanous, blackish brown, with a bronze gloss. 2 ♂♂ known, from Virginia and South Carolina. — The bag is cylindrical, spun with some bark. Size not stated.

17. Genus: **Fumea** Steph.

This genus has been dealt with in Vol. II, p. 367. It must be mentioned here, too, since a European species has been imported to America.

casta.

F. casta Pall. (Vol. II, p. 368 and pl. 55 i). Since 1931, this species is rather frequently found in Massachusetts and a part of Pennsylvania, where it was evidently imported. It was discovered while combating the *Ocneria dispar* L. Extensive breedings yielded in the ♂♂ predominating 10 by 1. Also in breeding *Eurycytharus edwardsi* and *celibata* it may occur that 30—40 ♂♂ emerge and not any ♀.

Family: Thyrididae.

Since the beginning of the present century our knowledge of the forms belonging to this strange family has increased enormously, yet we know very little to this day about the habits and the systematic connections of the different genera. The biology is known only of the sole genus occurring in Europe, while all the exotic species are known merely in their imago stage.

In dealing with the latter in Vol. X, p. 743, we had pointed out that there is an extraordinary variety in the habitus of this one, not very large family (WAGNER's Catalogue [by DALLA TORRE] enumerated about 500 species in 1914). A number of the species resemble the *Pyrilidae* not only in their shape but also in their attitude, in flying, in selecting their resting places, in their behaviour on being captured by the lantern etc., and besides they also show similar peculiarities in their anatomy. Others again are of a heavy, unwieldy build, assuming a beetle-like flight so that they might rather be taken for wood-bugs (*Pentatomidae* or *Scutelleridae*). In some (*Hepialopsis sphingipennis*, *Zeuzerodes fasciata*) we even find a Sphingid shape, then again the habitus of *Syntomidae* (*Diphya* [*Gippius*] *sumptuosus*, *Glanycus* etc.), the shape of *Noctuae* similar to the *Eutelia* (such as *Dysodia*), such of a Geometrid exterior as for instance *Rhodogonia miniata* and *Macrogonia*. Besides there are quite a number of species exhibiting most strangely shaped wings and bodies that are unparalleled in the whole lepidopteral kingdom, for instance *Zeuzerodes fumatilis*, *Draconia denticulata*, some *Risama* etc. Moreover, there is often a strange harmony in the outward appearance of some species the habitats of which are sometimes situated in quite a different part of the world, and which exhibit also an entirely different anatomy. This is not so very astonishing in those cases where such species belong to the same genera distributed over several continents, yet it is rather difficult to believe in a very close interior affinity between *Rhodoneura triumphans* from Ecuador and the quite similarly marked *Rhodoneura pudicula* from the Moluccas. But it is rather strange to see how the very same, sometimes quite abnormal coloristic designs are repeated in altogether different genera living in quite different continents. A man meeting a *Morova subfasciata* in New Zealand may imagine to be transferred to Pennsylvania, where he started the common *Herxeris enhydris* from the bushes, showing the very same shape, colour and marking of the wings. Yet it is not astonishing if adaptations to the same objects lead to the same transformations and developments in different animal groups. Thus *Risama falcata* seems to be adapted to the same shape of a leaf as many Geometrids of the genus *Oxydia* are, and since, according to the well known theorem, two objects resembling a third must also be similar one to the other, it would be entirely wrong to presume mimicry in such cases or to regard their geographical separation as a criterion opposed to this theory.

The family has undoubtedly nothing whatever to do with mimicry. On the contrary, as we have just mentioned, it abounds extraordinarily in quite uncommon shapes of the wings and no less in the designs of colouring. We do not exaggerate if we say that the design of *Herdonia*, for instance *Herdonia miranda*, is unknown in the whole other insect kingdom. *Risama picta* and *Draconia peripheta* are in America just as unmistakable lepidopteral forms as *Camptochilus sinuosus* in India and *Psycharium pellucens* or *guttulosa* among the African *Thyrididae*.

Several monographies and catalogues have already been published on the *Thyrididae*, thus in 1892 a monography on the "*Siculidae*" (a name for the group more commonly used by older authors such as LEDERER, GUENÉE) by PAGENSTECHER; besides a Catalogue by HAMPSON in 1897, and Pars 20 of the *Lepidopterorum Catalogus* by DALLA TORRE in 1914. The figures, however, which were at disposal till the corresponding volumes of the "*Macrolepidoptera*" appeared, were extremely scanty; on the one hand because only 1 or 2 specimens have become known of a relatively great number of species, mostly by reason of their being very rare or living in excellent hiding places; on the other hand, many species were represented by badly preserved specimens which made it impossible to supply a precise figure. The privilege of being able to publish for the first time such a vast number of figures (altogether more than 340 figures of *Thyrididae* and 150 for the American

species) we chiefly owe to the kind assistance of the owner of the great Tring Collection from which Dr. JORDAN had the great kindness to get coloured photos made of the types and to lend us double specimens for being figured. We therefore beg to express here our special thanks to Lord ROTHSCHILD and Dr. JORDAN for enabling us to provide more than 70 figures which could otherwise not have been procured. A further part of models for our plates we owe to the collaboration of Prof. Dr. M. HERING who got types painted in the Berlin Zoological Museum and supplied us with double specimens which were copied, an essential furtherance for the illustration of this difficult family.

In looking for the junction of the *Thyrididae* on the pedigree of the *Pyrallidae*, HAMPSON seems to have been correct in ranging them after the *Chrysauginae*. Only in the *Chrysauginae* do we find again the enormous variety of shapes of the *Thyrididae*, the uncommonly clumsy and bulky *Neophrida* and *Idnea*, beside the typically Pyralid-like slender *Bonchis* and the *Alpheias* exhibiting almost the exact shape of *Crambus*. We find the almost just as varied distortion and twists of the wings in the *Zanclodes*, *Itambe*, *Acropteryx*, *Rucuma*, *Oryctopleura* and many others, where the tips and dents of the wing-margins are often bent over the surface in the resting imago which, owing to peculiar bands and folds, is forced to keep its wings in a most strange way. Where we notice vesicular humps at the base of the costal margin in *Risama picta* and *Vadata macroptera*, the *Chrysauginae* *Cadadupa* show lobular pads, the ♂♂ of *Rucuma* and *Casuarina* incumbent bags, the ♂♂ of *Azamora* hollowed cavities. The frequent inclination to hyaline spots exhibited by *Thyris*, *Glanycus*, *Dysodia*, *Risama*, *Rhodoneura*, *Draconia* etc. recurs in the (*Chrysauginae*) *Idnea*, *Itambe*, and in their beginnings as tingy spots in many other genera, while the monstrous development of the palpi of so many *Chrysauginae* occurs in the *Thyrididae* only in very slight beginnings, as for instance in *Hexeris*, *Herdonia* and *Pycnosomia angulata*.

If MEYRICK considers the *Thyrididae* to be an older main branch of the Pyralid tribe, his opinion is contrasted by the great differentiation mentioned just now. All the real Pyralid groups, excepting the *Chrysauginae*, exhibit a much greater consistency, especially also in shape, than the *Thyrididae* do, if we regard each of these branches separately, — the *Myelobiinae*, *Crambinae*, *Hydrocambinae*, *Pioninae* etc. The differentiation of the *Thyrididae* among themselves seems to be due to their phylogenetically inferior age. That they likewise descended from a very old root we have regarded as a fact above and concluded from its worldwide distribution.

Regarding the distribution of the *Thyrididae* over the earth we refer our readers to Vol. X, p. 743. Here we only wish to point out the remarkable scarcity of the nearctic regions in contrast with the neotropical regions where also the largest *Thyrididae* hitherto known occur, i. e. the *Draconia* and *Belonoptera*. Only for the sake of curiosity do we call our readers attention to the strange consistency of habitus between the brown *Draconia mirabilis* and the Geometrid *Macrotis netrix* Cr. (Vol. VIII, pl. 1 a). Marginal tips and a large irregular distal vitreous spot might be connected with this habit in the *Draconia* which, according to CRAMER's statements behaves in repose like a *Lasiocampa quercifolia*, the hindwing projecting over the forewing like a roof, so that the insect looks like a bundle of withered leaves. Such an explanation, however, will hardly prove correct in the Ocnochromine, since it holds its wings raised like those of the Rhopalocera.

1. Genus: **Thyris** Lasp.

This rather small genus has been largely dealt with in Vol. II, p. 371. The 5 species known are distributed over the Old World (3 species) and the New World (2 species), where they live in a temperate climate, confined to the northern hemisphere. No species are known from the Indo-Australian and South American regions. Type: *fenestrella* Scop. from Europe.

maculata.

Th. maculata Harris (= *perspicua* Wkr.) (173 a). Body dark bronze brown, the end of the patagia rusty brown. Wings blackish. Forewing with 3 dull reddish yellow spots at the costal margin. A circular hyaline spot at the cross-vein, from which a feeble reddish yellow line extends inwards to the inner margin. Submarginal line of reddish yellow dots vertical above the anal angle, slightly inserted behind the cell, double at the inner margin, sometimes there is yet a dot between this line and the cell. Median band of hindwing composed of a double spot, with numerous reddish yellow spots scattered behind it. 15 mm. United States. — The larva was described by DYAR only in 1924; it is of a stout and square build, light orange with round black tubercles with a few hairs. Head orange red, neck-shield large, orange edged with black, anal plate black. On Clematis in the turned over edge of a leaf.

lugubris.

Th. lugubris Bsd. (173 a) is somewhat less dark than *maculata*. Black. Thorax with white lateral spots, abdomen with a few white dorsal spots. Forewing with many white dots at the costal margin, median band composed of 2 white spots. Behind them a larger one and 3 smaller ones. Hindwing with a broader median band. A few dots before the margin. 18 mm. United States.

2. Genus: **Diphyia** Wkr.

The genus represents the Indian species of *Glanycus* in the Nearctic Fauna. The only species known exhibits a habitus very similar to that of Syntomids or Arctiids; among the latter group it is also quoted in older catalogues by the name of *Gippius*. Palpi short and thick, antennae of the ♂ tufted. Forewing more oblong than in *Thyris*. The cross-vein of the forewing very feeble. Veins 4 and 5, as well as 7 and 8 very close together at the base, 6 far below the upper cell-angle, 9 + 10 stalked. In the rounded forewing veins 4 and 5 are also near together, the cross-vein is absent, 6 and 7 from the upper cell-angle, 8 fused with the anterior edge of the cell. Only 1 species known.

D. sumptuosus Wkr. (173 a). Body and wings black. Thorax with red lines. Abdomen with red lateral spots and anal tuft. Wings somewhat lustrous brownish. Forewing with rows of lemon-coloured spots in the basal half. Behind them a few more spots at the costal margin and anal angle. Hindwing with but 3 or 4 spots at the margin near the anal angle. 35—40 mm. Mexico. *sumptuosus*.

3. Genus: **Dysodia** Clem.

In the Palaearctic Fauna only a single species penetrates to the confines. In addition there are 3 species from the Indo-Australian Region, while 9 species occur in Africa. HAMPSON, in his monography, enumerates only 3 species from America, but we must consider that he did not yet know the species described later by DRUCE in the Biol. Centr.-Amer. This improbable numerical proportion was greatly changed later on by WARREN and DYAR, who enumerated about 25 species. We follow the statements of DYAR who in dividing the group into such a great number of species is probably going too far, as the separation of *igualensis* Dyar shows. Yet one cannot tell which names of species denote merely forms, without having a number of specimens at hand. The species are frequently found described among the generic names of *Varnia*, *Pachythyris* and *Platythyris*. Type: *oculatana* Clem. from America.

1. Forewing with a whitish hyaline discal spot.

D. oculatana Clem. (= *plena* Wkr., *fasciata* Grt. & Rob., *montana* H. Edw., *aurea* Pagst.) (173 a). The ground-colour is yellow, traversed by fine red-brown lines. The transverse bands are red-brown. An indistinct band at the base. The interior band is uniformly narrow, rectangularly broken in the middle. The median band is broad at the costal margin, with a yellow spot at the costal margin, somewhat broken in the middle and then only half as broad to the inner margin. The submarginal band is bent behind the cell, somewhat narrower than the interior one. The hyaline spot on the hindwing anvil-shaped. Behind it 2 narrow red-brown bands, partly fused. 20 mm. Distributed from the United States to Venezuela, but rare. The larva on the leaves of *Eupatorium*. *oculatana*.

D. vitrina Bsd. differs from *oculatana* in its violettish red colour. The larva is said to mine in the branches of *Phaseolus*, which is out of question in the species of *Dysodia* and *Thyris*. The species has never been discovered any more. Reported from the United States. *vitrina*.

D. summargo Dyar. Ground-colour coppery brown, somewhat yellowish at the base and costal margin. The dense violettish brown reticular lines are inclined to form rings around a central dot. The bands are broad, uniform, rather parallel, dentately edged. The 2 interior bands somewhat bent, the exterior and submarginal ones almost straight. Margin distinctly notched in both wings. Discal spot of forewing narrow, oblique, that of the hindwing large, narrower in the middle. Hindwing darker at the costal margin and anal angle, the striation distinctly ring-shaped. 25—30 mm. Mexico. Rather common. *summargo*.

D. immargo Dyar. Ground-colour also copper brown, only at the costal margin very narrowly yellow. The reticular lines are fine and dense, the light interspaces punctiform. The bands broad, similar to each other, the submarginal band terminating into the margin. The hyaline spots as in *summargo*. Hindwing almost uniformly covered with violet reticular lines. The brown ground-colour is only punctiformly preserved. The submarginal band is especially distinct on the forewing beneath in *summargo*, whilst it is absent beneath in *immargo*. The latter is lilac brown beneath, the following *granulata* is straw-coloured beneath, also without the submarginal band. 21 mm. Mexico. Described according to a single specimen. *immargo*.

D. granulata Neumoegen. Body grey. Forewing greyish brown, with numerous orange red reticular lines forming ellipses, only the distal margin remaining grey. The hyaline spots are irregular. The median band close behind it greyish brown, broad at the costal margin, tapering at the inner margin. 5 straw-coloured spots at the costal margin, 2 before the band, 2 behind it, one in the middle. Hindwing coloured like the forewing. The hyaline spot much larger, indented on its interior side. Straw-coloured beneath with brown reticular lines and a brown median band. 23 mm. Described according to 1 ♀ from Arizona. — **igualensis** Dyar has been described as a species likewise according to but one specimen from Guerrero (Mexico). The differences are the following: ground-colour orange yellow, the body almost the same. The reticular lines form more streaks. Forewing with a broader main band enclosing the hyaline spot, the centre of the cell is crossed by a transverse streak. The hindwing is also marked streak-like. 19 mm. Later on, BARNES and BENJAMIN ascertained from a larger number of specimens from Pima Co. (Arizona) that the species varies from specimens *igualensis*.

still darker than the *granulata*-type to yellowish ochreous *igualensis* in all kinds of transitions, yet each of the forms may occur predominantly or exclusively at the two typical habitats, so that both the names may be maintained.

- monava*. **D. monava** Dyar. The submarginal band being broad in the preceding species is linear in *monava*. Ground-colour of both wings olive grey, strewn with straw-colour at the base, with dense dark reticular lines. The forewing with a small triangular hyaline spot in the cell. The band behind it dark, broad at the costal margin. The distal margin narrowly dark. The large hyaline spot on the hindwing is indented outside. The whole marginal area behind it dark. Submarginal line indistinct, interrupted. 1 ♂ from Zacualpan (Mexico).
- hypothyris*. **D. hypothyris** Dyar. The body is more slender than in the other species. Wings broad, bronze black. Forewing with a few yellow spots at the costal margin and in the centre of the wing below the cell. Similar spots in the dark median band of the hindwing. Both wings with large hyaline white discal spots, that of the forewing oval, that of the hindwing rounded quadrangular. Nothing is mentioned of a submarginal line on the forewing; it will be covered by the dark ground-colour. Violet beneath, the forewing with 2 black bands and scattered streaks. 15 mm. 1 ♂ from Guerrero.

2. Forewing without a whitish hyaline discal spot. If such a spot is present on the hindwing, it is not quite transparent.

- dioxzona*. **D. dioxzona** Dyar. Body partly dark greyish brown. The forewing yellowish with fiery red spots. The basal area fiery red, brown at the costal and inner margins, the interior band behind it, beginning below the costal margin. Reticular lines fine, dense. The main band oblique, broad, united with a first band from before the middle of the costal margin and a second band close at the end of the main band, forming a fork of it. Hindwing with a broad basal band. The hyaline spot narrow, despatching a basal ray from the lower edge. Exterior band broad, running obliquely to the anal angle. 22—24 mm. Mexico.
- nipsa*. **D. nipsa** Drc. (173 a). Body and wings reddish brown, the transverse bands somewhat darker. The interior band and the main band of the forewing are somewhat widened in front, the submarginal band uninterrupted, parallel to the margin. Hindwing with a luniform white spot without a prolongation to the base. Under surface lighter. 30 mm. Panama. I consider *nipsa* to be an *oculatana* without a spot in the forewing. The indistinct dark marking is the same in both the species. I have one specimen each at hand with and without a hyaline spot on the forewing, from Chiapas (Mexico); they would therefore have to be two species from different groups.
- angulisola*. **D. angulisola** Dyar. Ground-colour yellow with some copper red. Forewing with broad violettish brown bands; the interior one broad at the costal margin, filled rather dark. Submarginal band interrupted, the anterior part terminating into the costal margin near the apex, the other part forming a spot above the anal angle. Hindwing dark at the costal margin and in the basal band. The discal spot is angular, divided. The centre of the wing with fine reticular lines, broadly light, without intense lines. 25 mm. 1 specimen from Panama. — Three somewhat different specimens probably belong yet to this species. One specimen each from Costa Rica and Mexico has a darker hindwing; in the former the wing is uniformly dark, in the latter the light median stripe is narrow. The third specimen, from Peru, is more intensely copper red on the hindwing, the costal margin not darker. Both the hyaline spots are larger. DYAR himself thinks that *angulisola* may be identical with the following *thyridina* Fldr., which may be correct.
- thyridina*. **D. thyridina** Fldr. (173 a) was formerly combined with *speculifera* Sepp, but according to WARREN and DYAR they are different. The ground-colour is brownish ochreous, not orange red, the costal margin in both wings is broader dark than in *speculifera*. The reticular lines are finer, forming pale spots between the veins. The cellular spot of the hindwing is shaped as in *oculatana*, its 2 parts being united in the ♀, separated in the ♂. The dark band extends before the hyaline spot, not behind it. On FELDER's figure in his work "Reise der Novara", pl. 117, fig. 20, the anterior part of the submarginal band on the forewing extends near the distal margin, and not into the costal margin as in *angulisola*. This would be only a slight difference. According to 1 ♀ of *thyridina* from the Chanchamayo, which is before me by the kindness of Dr. JORDAN, the figure is wrong. The submarginal band is exactly like that described in *angulisola*. *thyridina* was described from Guiana, it occurs also in Colombia, Peru, Bolivia. 26—30 mm.

In the following species as far as *flagrata* inclusively, the submarginal band of the forewing ends at vein 3 or 4, or it is linearly continued at most. The median band of the hindwing is forked, a feeble branch extends to the anal angle.

- speculifera*. **D. speculifera** Sepp (= *aequalis* Wkr.) (173 b) shows the hyaline spot on the hindwing large, undivided. The median band on the forewing terminates pointed at the inner margin. The species is never recognizably figured. The original work shows an orange yellow insect and a reddish violet one. The main band on the forewing is extremely broad at the costal margin, narrower at the inner margin. An interior band and a basal one are very thickly painted. The costal margin is not darkened. The dark brown band on the hindwing encloses the large hyaline spot. 32 mm. Florida, Tropical America. — HAMPSON takes *flagrata* Wkr. and *thyridina* Fldr. to be synonymous with *speculifera*. According to WARREN, they are 3 different species. There are 5 specimens before me, which may be *speculifera*, because they do not fit to the descriptions of the other

species of this group. Two of them exhibit a large hyaline spot on the hindwing, whereas in two others it is divided by a dark vein. A fifth lacks the submarginal line on the hindwing, the hyaline spot being divided. The latter specimen, however, cannot be *derufata*, since the ground-colour is as reddish as in *speculifera*.

D. pyrsocoma Dyar differs from *speculifera* (173 b) in its broader bands. The wings are narrower, hued *pyrsocoma*, with fiery red. By this different colour it is distinguished from *olivescens* Warr. The discal spot on the hindwing is large in *pyrsocoma* and *olivescens*. 1 specimen from Costa Rica served as the type for the description.

D. confusata Warr. (173 b) has a smaller discal spot on the hindwing. The bands and lines are likewise *confusata*, broad. The reddish or brownish ground-colour is less extensive than in *speculifera*, darker. The broad main band shows at its interior edge in the centre of the wing a projection towards the base almost as far as the interior band. A specimen kindly put at my disposal by Dr. JORDAN shows merely a small angle there, but a dark line extends from there steeply to the inner margin. The same is the case in *olivescens* (173 b). The light places on the hindwing are still more reduced, because the bands are broader. The hyaline spot is small, 8-shaped. 28—30 mm. Ecuador. — The type shows a deep copper red ground-colour, but it may also be olive brown: *olivescens* Warr. (173 b) from the same habitat; it is a dark olive brown specimen without any *olivescens*, light places at all. The hyaline spot is large.

2 b. The hyaline spot on the hindwing is divided.

D. derufata Warr. (173 b) differs from *speculifera* in its ochreous colour, which is sometimes a little *derufata*, reddish yellow, only the abdomen being red. The reticular lines are finer, more regular, more forming short dark brown streaks. Especially distinct on the hindwing, where the dark submarginal line is entirely absent. The cellular spot is composed of 2 contiguous small round spots. 26 mm. Described according to 2 ♂♂ from Parana, but it occurs also in other parts of Brazil. DYAR states that the apex of the forewing is tinged with dark violettish brown as far as vein 6; it is so as far as vein 4. A vertical submarginal line extends from the anal angle upward to vein 4.

D. innubila Warr. resembles a *derufata* (173 b) with a very pale marking. According to the author, *innubila*, it is distinguished from *speculifera* by its darker, more uniformly copper red colour, for which reason the reticular lines are less distinct. The lower half of the broad main band are somewhat narrower. The apical area behind the oblique submarginal streak is broader and darker red, not clouded as in *speculifera* and *derufata*. Hindwing with 2 small dissimilar hyaline spots. 26—28 mm. Bolivia, Peru.

D. acrotoma Dyar. Reddish, the striation blackish. The main band on the forewing narrow, triangularly widened at the costal margin. A straight line through the apex from the costal margin to vein 4. Behind it apparently not dark as in *innubila*. Hindwing with a faint median shadow. The discal spot is composed of 2 small hyaline spots, from where a line extends to the inner margin. The marginal striation is distinct, with wide meshes. 28 mm. Described according to 1 specimen from Zacualpan (Mexico). Differences from *innubila* not mentioned.

D. flagrata Wkr. (= *floridana* Hulst.). According to WARREN, the species is not identical with *speculifera* (143 b) as HAMPSON presumed. The inner margin of the forewing is dark brown from the base to the main band. The latter is not broad, not strangulated in the middle as in *speculifera*, but at the costal margin it forms an almost square spot down as far as vein 5, and from its interior angle a dark oblique line extends to behind the middle of the inner margin, while an irregular line extends from the exterior angle to the anal angle. The cellular spot on the hindwing is divided, bordered outside by the black median line which is widened into a spot above the median vein. Under surface pale brown, the marking olive brown, the interior marginal half of the hindwing broadly yellowish. The reddish yellow ground-colour of the ♂ is covered in the ♀ by dark brown dusting on both wings. 26—32 mm. Venezuela, Colombia, Ecuador.

3. In the following species the median band of the hindwing is not forked. The striation is parallel. The hyaline spot on the hindwing varies in its shape.

D. nomima Dyar. The main band on the forewing is convex outside, distinguishing the species from *nomima*, the two following ones. Ground-colour dull orange slightly mixed with red, with fine reticular lines. The main band is widened at the costal margin. A fine transverse line at the apex and a short vertical one at the anal angle. Also the hindwing shows the median band broader at the costal margin, without any other contrasting lines. Only a single small white median spot. 22 mm. Described according to a single specimen from Vera Cruz.

D. lineata Drc. (169 a). Body and wings olive brown. Forewing with 2 narrow somewhat darker bands *lineata*, in the basal area. The exterior band is twice as broad at the costal margin as at the inner margin. Traces of a subapical band from vein 4 vertically to the costal margin. Hindwing with a large hyaline spot in the middle, a few punctiform ones between it and the inner margin. 24 mm. Mexico.

D. borro Dyar differs from *lineata* in 2 small white hyaline spots on the hindwing. Forewing dark *borro*, violettish brown, copper brown in the middle, reticular lines dark, inconspicuous. Interior line bent, with a

projection at the middle, besides a parallel line before it. The exterior band is broader, especially at the costal margin. A fine transverse line at the apex. Hindwing with a broad median band behind the hyaline spots. 24 mm. One specimen from Jalapa in Mexico.

sica. **D. sica** Drc. (173 a). This species and the following ones have no more a distinct exterior band on the forewing, but a spot at the costal margin, from which a line proceeds to the inner margin. Ground-colour orange. Two fine dark lines in the basal area. A brown postmedian spot at the costal margin, from the edges of which one dark line each proceeds meeting at the inner margin. A distinct apical transverse line terminates at vein 3, and a short line vertically above the anal angle. Hindwing with a faded dark median band, broader at the costal margin, from where a line extends to the anal angle. 26—28 mm. Described according to a series from Tabasco. My only specimen from Panama shows 2 separated hyaline spots on the hindwing, which are not mentioned nor figured by DRUCE.

4. The following species have no transverse line at the apex.

traumatias. **D. traumatias** Dyar. Leather brown, tinged with violet. Forewing with a light red spot behind the cell. Reticular lines fine, spotted. The exterior line is only marked by a dark triangle at the costal margin, without any other lines. Hindwing with a large hyaline spot, deeply indented, followed towards the inner margin by a yellow spot with red reticular lines. 23 mm. One specimen from Jalapa.

remie. **D. remie** Dyar. Reddish like *speculifera*, but the distal margins darker in both wings. The striation is coarse, the lines are thin, the exterior line proceeding from a triangular spot from $\frac{2}{3}$ costal margin on the forewing. Hindwing with a straight fine median line, with 2 small white spots before it. Probably only a form of the following species. 23 mm. Panama.

lusia. **D. lusia** Drc. (169 f). The description of the forewing agrees exactly with that of *remie*. DRUCE mentions also an apical line in his description, but according to the figure this is evidently no oblique line, but one of the numerous parallel lines, which is somewhat more prominent. Hindwing without the dark median line and the hyaline spots. 27 mm. Tabasco.

spissicornis. **D. spissicornis** Warr. (173 b). Yellowish red. Forewing tinged with olive brown at the costal and inner margins, the reticular lines and transverse lines faded, dark brown. The basal line and interior line narrow, the exterior band broader, projecting outward above the middle, darker in the submedian fold. 4 pale spots at the costal margin, one before the middle, the others behind it. Hindwing only with reticular lines, the inner margin somewhat yellower, without any olive brown colour. The cellular spot is divided, forming two fine dots at the two angles of the cross-vein. 28—30 mm. 3 ♂♂ known from Rio de Janeiro.

ingenicula. **D. ingenicula** Dyar. As this species as well as *spissicornis* differ from nearly all the others in their considerable size, it might be only a form of *spissicornis*. Ground-colour copper red with coarse and fine reticular lines. Costal margin and apex of forewing darker. The exterior band is broader at the costal margin, with a projection on both sides. Hindwing with a similar band which is absent in *spissicornis*, but there is only a single hyaline spot present. 32 mm. Venezuela.

callista. **D. callista** Dyar. Body and forewing light ochreous, yellow at the anal angle, the apex broadly violet as far as the middle of the costal margin and to the angle at the distal margin, enclosing 3 pale spots at the costal margin. Before this apical spot a band from the costal margin to the submedian fold, below it two oblique darker bands to the inner margin. Hindwing brownish ochreous at the base, yellow at the margin, the median band violet, broad, forked at the inner margin. The hyaline spot is large, square, indented, yellowish hyaline. 27 mm. Described according to 1 specimen from Venezuela.

4. Genus: **Herdonia** Wkr.

The genus has already been dealt with in Vol. II, p. 372, since one species, the typical one, occurs in India and penetrates into the palaearctic regions. Besides it the genus contains but 4 more species, all from America.

miranda. **H. miranda** Warr. (173 c). Pale brownish ochreous, with some reddish brown here and there. Black double streaks with traces of a green filling at the base of the forewing and also a little at the beginning of the costal margin. Less distinct streaks above the inner margin as far as the base of vein 2. From veins 6 to 1 an oblique dark greenish brown band, edged with white on both sides. A paler brown submarginal stripe, slightly blended below the apex, widened at the anal angle. Hindwing similar. The basal spots numerous, the greenish brown median band in front very broad. The submarginal band is ramified at the apex. The size is most variable in this magnificent species. 35—55 mm. Described according to 1 couple from Fonte Boa (Upper Amazons); we figure a couple (♂ from Tring from Jaragua, ♀ from the Senckenberg Museum from Joinville in Sa. Catharina). — *isoldae* Köhler is said to have a grey oblique stripe, lighter than the submarginal stripe. 50 mm. From Argentina. The slight difference may be merely individual.

thetis. **H. thetis** Drc. (173 b). The contours of the wings on the original figure and the marking on the hindwing agree better with *tristriata* Pag. and *quinquelineata* Warr. which we have dealt with in the genus *Rhodoneura*. *thetis* is very pale and scantily marked. Body and forewing yellowish white. Pale brown double streaks at the base and

a few from there to the distal margin below vein 2, some also at the costal margin. A steep pale brown band from near the apex to the margin at vein 2. Hindwing white, with 3 fine dark brown double lines, an interior one, a median one, and a submarginal one. One specimen (28 mm) known from the State of Vera Cruz.

H. botydana Wkr. Wings pale yellowish. Forewing with 4 oblique double bands, the 3 first of which *botydana*. are incomplete. The dots and spots are blackish. Hindwing with 3 bands the ends of which are incomplete, the third widened at the costal margin and enclosing a white spot there. 35 mm. Brazil. From the description alone nothing could be said positively about it, if HAMPSON had not placed the species here in his List.

H. brixifacies Dyar. Forewing olive grey with dark grey bands and shadows. Interior band bent, in- *brixifacies*. cised in the middle. Exterior band composed of a spot at the costal margin and a band below it, excurved behind the cell. Submarginal band divided in the middle, the anterior part more red-brown, the lower one forked towards a longitudinal row of black spots. Hindwing creamy white with brown bands. The interior one only as a spot, the middle one straight, forked at the costal margin, the exterior branch black. The submarginal band is distally removed in its anterior third, with a black spot in front of it. 17—22 mm. Panama. Described according to two specimens.

5. Genus: **Pycnosoma** Hmps.

Separated from nearly all the other genera by the third palpal joint being long porrected horizontally. Forewing broad, veins 7 + 8 short, 9 + 10 long stalked. On the hindwing veins 6 + 7 on a short stalk. The genus contains but one single species.

P. angulata Hmps. The size and reddish yellow colouring similar to *Rhodoneura furva* (173 e), but *angulata*. without the discal vitreous spot in the forewing. Body reddish yellow. Wings golden yellow, densely striated reddish. Forewing only with an exterior line, obliquely outward at vein 7 almost as far as the margin, then straight to behind the middle of the inner margin. Hindwing with a large dark middle spot with hyaline and brown spots behind it; similar ones towards the inner margin. Exterior line red-brown, bent, ending at the anal angle. 32 mm. Described according to 1 ♀ from Espiritu Santo.

6. Genus: **Mathoris** Gn.

The thin palpi bent up to the frons. Wings broad and short. In the forewing only veins 9 + 10 are stalked. In the hindwing vein 8 is bent so far downward behind the cell that it is fused with vein 7. 5 species occur in South America, besides 2 in Africa; cf. Vol. XIV, p. 497, pl. 75 i. Type: *vocata* Wkr.

M. vocata Wkr. (= *procurata* Wkr., *roseola* Fldr., *crepuscula* Gn.) (173 e). Ground-colour orange, with *vocata*. fine dark red-brown reticulate lines. Forewing with 3 small hyaline dots, one above the base of vein 2 and one above vein 3, the third in the middle between them above vein 1. The brown striation is fused into a median band which is broad at the inner margin, enclosing the two upper hyaline dots, then divided to the costal margin in a narrow interior branch and a broader exterior one. Red-brown spots in the marginal area. The hindwing may exhibit a larger hyaline spot near the base of the cell, with a narrow red-brown band behind it, and a broader one at the margin with spots of the ground-colour. 15 mm. Brazil, Cayenne.

M. mediaria Wkr. Described as a Geometrid, but placed here by HAMPSON. Apex of forewing pointed, *mediaria*. somewhat excavated below it. Ground-colour rusty brown. Both wings with black reticular lines, irregular and interrupted, with a single more prominent straight oblique line. 1 ♂, 28 mm. From the Amazon District.

M. apiceflava Dgn. Ground-colour brownish orange, with more or less regular lemon-coloured spots *apiceflava*. on the forewing below the costal margin and in the submedian fold, and in the distal half of the hindwing. These chessboard-like spots are produced by the veins crossing the transverse lines in the ground-colour. Forewing with a lemon-coloured spot below the apex at the margin, broad at veins 9—7, extending down to vein 5. Hindwing yellow at the margin between veins 7 and 3. 23 mm. 1 ♂ known from Cayenne.

M. multiguttata Hmps. (180 g). Owing to the shape of the wings and the scheme of markings, the species *multiguttata*. looks exactly like a species of *Rhodoneura*; it presumably belongs to the following genus. Body and wings dark red-brown. Thorax yellowish white. Forewing with about 5 yellowish white bands of brown-centred rings, besides a few indistinct bands and single rings. Hindwing with darker reticular lines in the basal area. Behind the middle from $\frac{2}{3}$ costal margin a narrow band of white rings, strongly widening towards the inner margin. ♂ 25 mm. Bolivia.

M. quadrigata Fldr. is placed here by DALLA TORRE, which is surely a mistake. HAMPSON has omitted it.

7. Genus: **Stenocopsis** Warr.

Similar to the preceding genus in its structure and neurulation, but the forewing is stretched, the costal margin straight, slightly bent at the pointed apex, distal margin oblique. Hindwing with a pointed apex and a short inner margin. Only 1 very small species.

albiapicata. **S. albiapicata** Warr. (173 d). Wings ochreous. Forewing dusted black with a dull reddish yellow marking. Costal margin and inner margin reddish yellow as far as the submedian fold. A narrow interior band, then one before the middle of the wing, a broader one behind it, slightly bent inward in the middle, and a narrow undulated submarginal band. An oval white spot with a black central dot, a fine black submarginal line beginning outside at this spot, anal angle whitish. Hindwing with a slight grey hue, with traces of 3 parallel bands; a basal band of black scales, a brown median band, a fine indistinct submarginal shadow. ♀ 16 mm. From the Orinoco R.

8. Genus: **Macrogonia** H.-Schäff.

Palpi thick, projecting beyond the frons. Forewing slightly angular at the middle of the distal margin, not any vein stalked. Hindwing also angular in the middle. Veins 6 and 7 from the upper angle. Type: *igniaria* H.-Schäff., besides two other species.

igniaria. **M. igniaria** H.-Schäff. (173 c). Ground-colour orange with fine pink reticular lines. A blackish line edged with pink on both sides from the middle of the inner margin of the hindwing towards the apex of the forewing, shortly before the latter bent round to the costal margin and indistinct. 25 mm. Brazil. Apparently rare.

major. **M. major** Schs. Thorax pinkish yellow. Forewing yellow with pink reticular lines. Costal margin with dark spots which are more densely arranged in the first part. A fine brown line at the base and an undulated interior line. An indistinct ring at the cell-end. A fine black line from near the apex to the middle of the inner margin, continued on the hindwing as a median line. A few black reticular lines at the margin. Hindwing dark pink, exterior line fine, black reticular lines also at the margin. ♀ 32 mm. Costa Rica.

lucida. **M. lucida** Warr. (173 c). Body brownish ochreous with reddish orange spots. Wings brownish ochreous with reddish orange reticular lines. Forewing with a quadrangular dark brown spot behind the cell between the subcostal vein and vein 5, a line extends from it to an irregular brown oblique line from vein 7 to the middle of the inner margin, which latter line meets another oblique line extending from $\frac{5}{6}$ costal margin to the distal margin. The rest of the wing is covered with reddish orange reticular lines. Hindwing pale at the costal margin. The interior line dark brown from vein 6 to the inner margin, continuing the main line of the forewing. Veins thickly reddish orange, the reticular lines partly brown. 28—30 mm. A few specimens from the Upper Amazon R. — A specimen from the Senckenberg Museum exhibits a somewhat plainer marking. The costal-marginal spot is isolated. The main line from the centre of the inner margin on the hindwing extends towards the apex of the forewing as in *igniaria*, but it is more sharply bent inward to the costal margin than in the figure of *igniaria*; *lucida* is probably not specifically different from *igniaria*.

9. Genus: **Striglina** Gn.

The species of this genus occur in all the Faunae, though only one in the palaearctic Fauna (*scitaria*, cf. Vol. III, p. 373 and pl. 50 f). Most of the species are Indo-Australian, while 8 species are known from the warm districts of America. Type: *scitaria* Wkr. differs from the preceding genus in its feebler palpi. The margins of the wings without angles. All the veins of the forewing free, veins 6 and 7 of the hindwing arise distantly separated. Cf. also Vol. X, p. 746; Vol. XIV, p. 495.

ochracea. **S. ochracea** Mschlr. is very insignificant. Body and wings pale red-brown. The only marking on the forewing above is a white streak at the cross-vein with a small dark spot outside. Forewing beneath reddish, very intensely so in the marginal area. Hindwing dark orange yellow with many rows of indistinct pink streaks. Under surface and legs very much like those of the next species. ♀ 42 mm. Surinam, Amazons.

rufitibia. **S. rufitibia** Fldr. (173 d). Body and wings brownish ochreous with a slight greenish shine and numerous darker brown streaks on the forewing. Traces of an interior line above $\frac{1}{4}$ inner margin. A dark spot at the cross-vein, indistinct in the ♂. The exterior line from the apex to the middle of the inner margin is indicated by the darker distal area. Hindwing with a feeble dark median band and a few dark streaks. The ♀ is more intensely reddened, the cellular spot on the forewing is more distinct. Forewing beneath dark red with an exterior line of thick black spots, hindwing orange, somewhat red at the base, with few dark spots. 38—45 mm. Peru, Amazons, Guiana.

brunneata. **S. brunneata** Warr. Olive brown with few black spots. An indistinct dark line from the apex of the forewing to the middle of the inner margin on the hindwing, where the line is broader, apparently double. Black scales at the apex of the forewing. Ground-colour beneath duller, the striation more distinct, the inner margin of the forewing pale, the oblique line absent. 1 ♂, 24 mm, known from Cayenne.

S. flammans *Hmps.* Body and wings fiery red, only the tips of the patagia and the centre of the abdomen brown. Forewing with numerous brown reticular lines. An almost triangular brown spot behind the cell, from which an oblique line proceeds, which widens below vein 2 and is divided at the inner margin. A brown line from the costal margin behind the middle obliquely outward as far as vein 5, slightly bent inward at vein 4, terminating at the anal angle. Hindwing also with dark reticular lines. A brown spot below the middle of the costal margin, with an adjoining line to the inner margin. Under surface pale brown. ♀ 32 mm. Peru. *flammans.*

S. jucunda *Warr.* (173 d) is of a quite different exterior. Body brown and somewhat red. Forewing brown and more intensely red. Below the margin pairs of large yellow spots and a small one between them. From the first pair at $\frac{2}{5}$ costal margin a finely curved red line extends to $\frac{1}{3}$ inner margin. From the second pair at $\frac{2}{3}$ costal margin and a single dot behind it a yellow straight forked line extends to $\frac{2}{3}$ inner margin, parallel with the distal margin which is reddened below the middle. Round yellow spots at the apex and distal margin, a larger one between veins 4 and 5. Hindwing reddened only at the base as far as an irregular yellow line from which sometimes two similar lines extend to the distal margin below the middle, the lower one being slightly interrupted. The marginal area with large and small yellow spots. Under surface liver-brown, without red patches, the yellow spots strongly developed, the exterior line yellow, the margin behind it brown, with but few spots. ♂ 24 mm. Some specimens known from Peru and the Upper Amazon R. *jucunda.*

S. xanthopera *Hmps.* Body and wings pinkish brown, with thick yellow spots. Forewing with a bright yellow spot at the costal margin before the apex. A yellow, distally dark-edged line from the apex of the forewing to the middle of the inner margin on the hindwing. 1 ♂, 28 mm, from Rio de Janeiro. *xanthopera.*

S. medara *Schs.* Body and wings claret-coloured, densely spotted blackish brown, forming rings and streaks, and strewn with red. Distal margin undulated, projecting in the middle. Forewing finely white at the costal margin. A small dark ring in the cell-end. Hindwing with small hyaline spots, forming an interior row and a middle row. The under surface flesh-coloured with red-brown ring-spots between the veins. ♂ 36 mm. Rio de Janeiro. *medara.*

S. pyrostola *Hmps.* (173 d) shows still more differently shaped wings. The distal margin of the forewing is cut out below the apex, excurved in the middle. Hindwing slightly angular at vein 4. Body fiery red. Forewing densely striated and tinged with fiery red. Behind the cross-vein an oblong black spot from which an indistinct oblique red line extends to the inner margin. A few dark streaks at the end of the submedian fold. Hindwing fiery red with some yellow spots. Base and inner margin pale yellow. An oblique blackish median line with a yellow spot behind it in the cell-fold. Fringes of both wings blackish brown. Yellow beneath with numerous fiery red and a few black strigae. Forewing with black spots behind the cross-vein and in the centre of the submedian fold. ♀ 42 mm. Guiana. — It may be that this species is identical with the previously described *Rhodogonia miniata* *Warr.* (173 d). A specimen from the Senckenberg Museum shows the conspicuous yellow spot of *pyrostola* on the hindwing. The red line on the forewing, however, as well as the median line on the hindwing are absent. The specimen differs only in the yellow spot from a distinct *miniata*. *pyrostola.*

10. Genus: **Hypolamprus** *Hmps.* (*Betousa* *Wkr.*)

The genus contains small species with narrow wings, nearly all of which are Indo-Australian, while 3 species occur in Africa and only 2 in South America. Cf. Vol. II, p. 373; Vol. X, p. 749, and Vol. XIV, p. 494 (*Betousa*). Type: *striatalis* *Swh.* from India.

H. parisignata *Warr.* Similar to *Symphleps ochracea* *Pagst.* from Aru (Vol. X, p. 771), of about the same size, with somewhat narrower wings, paler ochraceous. Both wings with two black spots at the cross-vein, surrounded by black scales, but both wings are without the black marginal dots. Costal margin of forewing somewhat darker. Wings traversed by densely arranged dark lines as in *ochracea*. 22 mm. Described according to a couple from Surinam. *parisignata.*

H. stellata *Schs.* Body and wings greyish brown, with greyish white streaks and spots. The streaks in the basal third of the forewing are divided into spots by the veins, edged darker brown. The middle, exterior and submarginal rows of spots are edged darker, with black dots. The spots are divided into 5 or 6 parts by the transverse lines, those at the costal margin being smaller and less distinct. The exterior row is inwardly bent and almost fused with the middle row. Besides smaller divided spots right at the margin itself. On the hindwing the spots are smaller, whiter at the inner margin, only the exterior and submarginal rows are centred dark. Wings broad, with a bent distal margin. ♀ 40 mm. Costa Rica. *stellata.*

11. Genus: **Letchenodes** *Warr.*

Exactly like *Rhodoneura*, but veins 8 + 9 of the forewing are stalked as in *Hypolamprus*, so that the new genus seems to be really superfluous. Only 1 species.

L. ninniusalis *Wkr.* Body greyish brown, wings violettish brown. Forewing rather pointed at the apex, with short black lines at the costal margin. A group of bluish white hyaline spots in the centre of the wing, *ninniusalis.*

the transverse lines brownish ochreous. Two black spots at the inner margin near the base. Hindwing with black lines of the inner margin and the neighbouring distal margin. The hyaline spots are less numerous than on the forewing. ♀ 28 mm. Amazons. Only this one specimen seems to exist.

12. Genus: **Rhodoneura** Gn.

Only a small number (about 6 species) of the approximately 300 species of this genus occur in the palaearctic regions and also only at the limits of the fauna in China and Japan. A larger number of species occur in Africa, and the rest is divided among the Indo-Australian and American Faunae (77 species). All that is necessary has already been told about the genus in Vol. II, p. 373, moreover in Vol. X, p. 754, and Vol. XIV, p. 491. In both wings there are not any veins stalked. Type: *pudicula* Gn. from Java.

1. Antennae of ♂ pectinnated, of ♀ serrated.

sparsireta. **R. sparsireta** Hmps. (180 h). Pale yellow, the lines red-brown. Forewing with a slightly excurved interior line. The median line somewhat stronger, forked at the costal margin, then obliquely inward, straight, slightly split also at the inner margin. The exterior line straightly outward as far as vein 6, inward as far as vein 3, outward to the submedian fold, where it is broadly forked. The upper angle is almost touched by the inwardly bent oblique apical line. Hindwing with a fine bent median line, the exterior line similar to that of the forewing. Both wings besides with fine reticular lines. Beside the type there is another larger, darker ♂ at hand, densely covered with uniform lines. ♂ 18 to 28 mm. Cuba.

2. Antennae of ♂ only thickened.

terminalis. **R. terminalis** Wkr. Pale reddish grey, with reddish spots, abdomen very long. The narrow forewing is rounded at the apex. A short black bent streak at the cross-vein. Hindwing with a pointed apex, the streak at the cross-vein shorter. 35 mm. San Domingo.

tigridula. **R. tigridula** Gn. (173 e). Forewing with a pointed apex and an angle at the middle of the distal margin, hindwing triangular. Both wings reddish brown, densely covered with lighter lines, not reticularly connected, but forming elongate rings. 32 mm. Cayenne.

acygoniata. **R. acygoniata** Hmps. (180 h). Both wings with a pointed apex and angled at the middle of the distal margin. Pale red-brown with somewhat darker red-brown bands and a few lines. Somewhat darker at the base. Interior band extra-angular below the inner margin, then somewhat inward to the inner margin. Exterior band somewhat more extra-angular below the costal margin, then parallel with the interior band to the interior margin, distally forked above the inner margin. An angled apical band behind it, and a submarginal band beginning from vein 4. Hindwing with a somewhat darker interior and median band, narrower in the middle. Dark at the distal margin, very broad in front, ending pointed at the marginal angle. A feeble submarginal band behind it. ♂ 32 mm. Colombia.

configurata. **R. configurata** sp. n. (173 f). Similar to *acygoniata* in the shape of the wings and the scheme of markings, but larger, darker, more reddish. The angle on the hindwing is somewhat more rounded. Ground-colour somewhat hyaline. The interior band of the forewing projects considerably below the cell, not close under the costal margin. The median band is an oblique wedge ending pointed behind the base of vein 2. The exterior band is very much wider at the costal margin and especially at the inner margin than in *acygoniata*, otherwise similarly shaped. The margin from the apex to vein 4 is narrowly red-brown, then broader, but enclosing light spots of the ground-colour, united with the exterior band at vein 1. Besides there are single red-brown lines distributed over the forewing. Stronger red-brown reticular lines in the basal area of the hindwing. The median band is present only in the anterior part, then broken up into lines. Apex broadly red-brown, similarly extensive as in *acygoniata*. The wing is covered with coarsely reticulated lines behind the median band. Ground-colour beneath yellow, the marking as above. ♀ 45 mm. Brazil. Type in the Senckenberg Museum.

mescememna. **R. mescememna** Dyar shows the much smaller angle on the hindwing below the apex. Ground-colour lilac. Forewing with a few rows of black streaks. White at the apex with a black spot. A quadrangular red spot with black corners is at the cross-vein. Exterior band broadly red, widened at the costal margin. Marginal area with a reddish hue. Submarginal line dark, parted blackish at the angle of the wing. Hindwing dusted black and red in the interior third, divided before the middle by a reddish band which terminates as a white streak at the margin below the angle. 19 mm. Panama. Two specimens were found.

leucosticta. **R. leucosticta** Hmps. Hindwing incised at the margin from the apex to vein 4, then excurved. Body dark brown. Forewing red-brown, dark brown in the marginal area, with a silvery lustre. Four indistinct narrow bands of dark streaks extend through the cell. Short black streaks behind the cell. An oblique dark median band from the cell to the inner margin, adjoining to it small white quadrangles in the submedian fold. The exterior band from vein 6 obliquely to the inner margin, the submarginal line indistinct, bent. Hindwing pale red-brown, densely striated darker, forming reticular lines. Black dots at the base, at the cross-vein and in

the middle of the inner margin. Besides a narrow median band to the anal angle. The apical spot is dark, its interior edge bent. 1 ♂, 30 mm, from British Guiana.

R. ophiographa *Hmps.* Body and wings red-brown with a violet shine and somewhat whitish. Fore-*ophiographa*. wing with darker brown strigae. Interior band oblique, pale, laterally edged with black and white lines, extending to the median vein, a round white spot below it. A similar median band from the costal margin to the inner margin, with undulating edges, widened at the costal margin and enclosing a small red-brown spot at the costal margin. Exterior band forked at the costal margin, broader below vein 2, extra-angular behind the cell. A black spot at the lower cell-angle. Submarginal line fine, black, obliquely inward at the apex, forming oblique pale-centred spots at veins 4 and 3. Hindwing with a basal and median band of white spots edged with dark brown, a small white postcellular spot behind the median band. Exterior band of irregular spots. 38 mm. Peru, described according to two ♂♂.

R. euprepes *Hmps.* Body and wings pale rusty brown. Forewing with a silky gloss, with numerous *euprepes*. uniform indistinct red-brown strigae. Hindwing with an oblique red basal line. ♀ 20 mm. British Guiana.

R. myrtaea *Drury* is preferably Indian and distributed as far as the Sunda-Islands. Cf. Vol. X, p. 755 and pl. 91 k. It seems doubtful whether it really occurs in the West Indies.

R. furva *Warr.* (173 e) may be merely a form of *myrtaea*. Thorax iron grey, abdomen brick-red. Fore-*furva*. wing light reddish brown, lighter at the costal margin, with numerous dark faded short transverse streaks. An indistinct dark spot at the cell-end, a silvery hyaline black-edged spot below it under vein 3. Hindwing slightly darker, redder, the cellular spot black. 26 mm. San Domingo, Cayenne.

R. myrsusalis *Wkr.* (173 e) is also widely distributed, similar to *myrtaea*. It has been treated upon in *myrsusalis*. Vol. X, p. 755 and pl. 91 k, and also figured in Vol. II, on pl. 56 f. Further names given to specimens from the South-American Regions are: *cinereola* *Fldr.*, *radiata* *Pagst.*, *scallula* *Gn.* Body and wings greyish brown with dark strigae. — **flavalis** *Dgn.* is ochreous with much less striation of a pinkish brown. Forewing with *flavalis*. many white spots. A large one below the base of vein 3; besides 4 smaller spots below vein 2, all of which are edged with pinkish brown. Moreover a spot between veins 5 and 6 behind the cell, and 3 at the margin, two of which are in the middle, one at the anal angle. Cayenne. — **immaculata** *Mschlr.*, contrary to *flavalis*, *immaculata*. shows no light spots at all. Porto Rico, Brazil. — We figure a ♀ from Brazil, taken by ZIKAN in the Itatiaya Mts. on the 26th of November 1926.

R. gilva *Hmps.* Body and wings creamy white, slightly tinged with red-brown. Forewing more in-*gilva*. tensely red-brown in the basal area and at the costal margin as far as beyond the middle. A few dark dots at the costal margin. The interior and median lines of brown streaks. A small square hyaline spot below the cell-end, laterally edged with brown. Exterior line of brown double streaks, filled with red-brown between veins 3 and 1. A series of dark brown streaks from the costal margin near the apex to the margin at vein 1. Hindwing with a few red-brown streaks and a curved brown median line. ♂ 14 mm. Sa. Lucia.

R. extravagans *Warr.* (173 e) is also allied with *myrsusalis*. Greyish brown with dense dark strigae. *extravagans*. Forewing with a brownish orange spot in the middle between the subcostal and submedian veins, containing several whitish hyaline spots between the veins, besides a few spots in the submedian fold. Hindwing without markings. ♀ 30 mm. Upper Amazon R.

R. pammicra *Dyar.* Bronze brown with dark brown reticular lines. Forewing with 2 lines forming *pammicra*. an exterior band widening at the costal margin, one of the lines being distinct and straight. Hindwing with stronger reticular lines enclosing a pale elliptical spot which extends to the costal margin, and one at the anal angle. Besides a few fine streaks. 14 mm. Taboga I. (Panama).

R. amethystea *Fldr.* (173 g) seems to be little known and may be identical with *aurifera* *Hmps.* which *amethystea*. was placed far off by HAMPSON. We describe the species according to FELDER's figure. Forewing reddish brown with a violet shine and few dark reticular lines. Yellowish white spots at the costal margin, an oblique rectangular one before the middle as far as the lower cell-angle, adjoining to it inside a narrow spot as far as the base. A flatly triangular spot behind the main spot, and an obliquely cut off apical spot. Hindwing paler, with few and fine reticular lines. ♂ 30 mm. Amazons.

R. nebulosa *Warr.* (= *rotundula* *Pagst.*) (173 f). One of the commonest species. Body and wings in-*nebulosa*. tensely red-brown with ochreous bands and spots of variable extensions. Forewing with a yellow median band, broad at the costal margin, extra-angular below it; then narrower vertical to the inner margin. Yellow spots before it towards the base, almost absent or also in numbers. An exterior band of round yellow spots, often with black scales inside, the band extra-angular at vein 6, mostly interrupted above it, often double below the angle. An isolated spot at the margin below the apex. Hindwing mostly more ochreous, with blackish brown spots and scales behind the cell. Traces of a red-brown median band at the inner margin. 42—60 mm. Brazil, Bolivia, Peru.

- apicalis*. **R. apicalis** Pagst. (= *erythrinalis* Pagst.) (173 e) looks almost like a small lighter *nebulosa* (173 f). The white apex is quite straightly cut off. 30 mm. Peru, apparently not rare in Costa Rica. *hedilalis* Wkr. is also very similar to *apicalis*.
- bullita*. **R. bullita** Hmps. Body and wings dark red-brown. Forewing with numerous small round white spots. The ground-colour forms indistinct interior, median and exterior bands. The median band is widened at the cell-end, a fourfold row of spots behind the exterior band between veins 6 and 2. The apical spot as in *nebulosa* (173 f). Hindwing also with numerous white spots between which the ground-colour forms indistinct bands. Black patches below and behind the cell as in *nebulosa*. 52—56 mm. 2 ♂♂ known from Peru.
- hedilalis*. **R. hedilalis** Wkr. Thorax and forewing reddish brown with an ochreous marking. A bent median band does not always reach to the inner margin. Next to it, partly fused with it, faded below vein 5 as far as the distal margin, brownish ochreous, only in the middle of the inner margin there is yet a more or less isolated notch of the red-brown ground-colour. A sharply cut off light spot at the apex. All the yellow places with fine red-brown reticular lines. Hindwing ochreous, somewhat reddish. The beginning of a red-brown band at the middle of the inner margin. A distinct black dot at the cross-vein. The whole wing with fine dark reticular lines. 26—35 mm. Chiriqui, Peru, Brazil.
- mesosticta*. **R. mesosticta** Hmps. Body pale yellowish brown. Wings whitish, densely striated with pale yellowish brown lines. A somewhat distinct median line, slightly incurved in the cell, then undulate. A brown spot between it and the exterior line above vein 1, then a brown spot at the costal margin; at the ends of the cross-vein 1 black dot each. Exterior line brown, incurved as far as vein 5, where it is extra-angular, more inward as far as vein 3, in the submedian fold near the median line. From the exterior line, at vein 5, a branch proceeds to the submarginal line in the submedian fold. Submarginal line undulated. Two dark spots at the costal margin near the apex. Hindwing whitish with dense yellowish brown reticular lines. Three more distinct lines in the median area from vein 2 to the inner margin. A black dot at the lower cell-angle. ♀ 44 mm. Peru.
- fulviceps*. **R. fulviceps** Fldr. (173 g). Head and end of abdomen yellow, all the rest dark violet. Both wings with numerous dark brown thick and irregular transverse lines. 28 mm. Amazons.
- lunula*. **R. lunula** Fldr. (173 f) is a large, beautiful species with most remarkable dark reticulations. The genus *Belonoptera* H.-Schäff. differs from *Rhodoneura* only in the very pointed apex of both wings. In *lunula* the hindwing is much more pointed than in the other *Rhodoneura*, but as the forewing is normal, the species remains better here, although WARREN places it to *Belonoptera*. Body and wings dark orange, with numerous fine dark brown reticular lines. The forewing besides with an interior line, at first extending outward at the median vein, then bent round and very obliquely inward. Median band formed by a bundle of lines, straight, very obliquely inward, forked at the costal margin and inner margin. Behind it at vein 3 a spot from which a short line extends to the anal angle. A straight line from the costal margin near the apex to the margin at vein 4. Hindwing with a line from the middle of the costal margin to $\frac{2}{3}$ inner margin, a thick silvery spot close behind it at the cross-vein. A spot at vein 3 as on the forewing also with an adjoining line, and an apical line. 65—70 mm. Brazil.
- trigoniphora*. **R. trigoniphora** Hmps. HAMPSON ranges this small species after the gigantic *lunula*, though it seems to be more allied to *anastomosalis*. Wings red-brown, with a golden gloss, with darker reticular lines. Forewing with 3 grey triangular spots at the costal margin, and grey at the apex. Of the numerous transverse lines there are two exterior ones more prominent, distantly separated at the costal margin, united close above the inner margin. Besides an oblique submarginal line. Hindwing with two white spots at the cross-vein and a dark spot above the middle of the inner margin. ♂ 22 mm. Brazil.
- oxydata*. **R. oxydata** Jones (173 e). Body dark brown. Forewing lighter brown, silvery spots at the costal margin are formed of hair-lines, and a few similar ones at the inner margin in the basal area connected by some silvery scales. A dark red-brown oval spot, divided by bluish, situate above $\frac{3}{4}$ inner margin, extending to the upper cell-edge. Three yellow metallic spots behind the cell, a larger one at the anal angle. Small silvery blue spots at the margin. Hindwing brown. Fine blue lines at the base, blue dots and rings also in the apical area. A red-brown band from the middle of the inner margin almost to the costal margin, a black spot behind it in the submedian fold, the anal area behind it brass-coloured. Near the apex a large red-brown spot and a few small ones. 26—30 mm. Type ♂ from Santos. We figure a ♀ from the Itatiaya from the Senckenberg Museum.
- albipunctula*. **R. albipunctula** Pagst. (180 g). By the long abdomen it resembles the two following otherwise quite different species. Body and wings brown with a slight reddish lustre. The only marking on both wings are two black dots at the cross-vein, beside dark dots distributed over the wings and somewhat less dark fine lines. Hindwing with a rather pointed apex. ♂ 22 mm. Peru.
- gracilis*. **R. gracilis** Mschlr. (173 g). This species and the 3 following ones differ besides from the others in their very narrow forewings. The type from Surinam is not very well preserved, for which reason my description refers to another specimen from Bolivia. Body light red-brown. Forewing also red-brown as far as a line vertically on the middle of the inner margin. Exterior band somewhat darker, slightly inward, somewhat

wider at the inner margin, more than twice as broad at the costal margin, where it is inwardly fused with the basal area. Inside of the exterior band golden yellow, broader in the type than in the second specimen in which also the inner margin is brown there. This area well as the whole marginal area with fine dark lines, the second specimen with a distinct subapical line. Hindwing golden yellow with a strong red-brown median line and reticular lines. 17—19 mm. Surinam, Bolivia; from Goyaz (Brazil) a faded marked specimen without any light median area.

R. ferruginea *Pagst.* (173 f). Body and wings rusty red. Forewing violettish red behind a line from *ferruginea*. the apex to the lower cell-angle and to $\frac{1}{3}$ inner margin. Hindwing narrowly red in the lower half at the distal margin. The rest of both wings without any marking. ♂ 22 mm. Chanchamayo, Goyaz.

R. sectilinea *Warr.* (173 g) is remarkable for its extremely pointed forewing. Body brown, wings straw- *sectilinea*. coloured. Forewing with fine brown reticular lines. Small brown triangles at the costal margin and an oblong spot at $\frac{3}{4}$ costal margin. Apex broad, brown, triangular, as far as the middle of the distal margin, edged with dark inside, connected at vein 5 with a straight brown line from the middle of the costal margin. Slightly brownish at the middle of the inner margin and at the anal angle. Hindwing with a feeble brown median band with a black spot at the cross-vein. ♀ 24 mm. Upper Amazon R.

R. semierma *Schs.* Body olive brown, wings reddish brown. Forewing grey and olive brown at the *semierma*. costal margin as far as into the cell. Interior line dark brown, introangular in the cell, with opalescent scales. irregular fine brown lines behind it. A large black shadow behind the cell-end, narrowest between veins 6 and 9, fused below vein 6 with a dark exterior line from the costal margin. A brown shadow below vein 3, ending pointed at the inner margin. The exterior line is edged with grey and silvery white on both sides at the costal margin, a dark longitudinal streak is behind it above vein 8. Distal margin brown from the costal margin to vein 3, bent inward at the veins, grey before it. Hindwing spotted brownish and black, especially in the basal area. Near the inner margin a large black spot in the middle and behind it. ♀ 44 mm. Costa Rica.

R. umbrata *Schs.* Body and forewing dark brown. A pale yellowish red shadow below the cell as far *umbrata*. as the submedian fold and the distal margin, densely spotted dark as far as the middle, then less so. A similar broad shadow at the distal margin between veins 6 and 4, with indistinct dark lines. Hindwing broadly dark brown at the costal margin, edged below by an undulate white line. Lilac towards the anal angle with fine brown spots. ♀ 32 mm. Costa Rica, described according to a single specimen like *semierma*.

R. thiastoralis *Wkr.* This species has already been dealt with in Vol. X, p. 764. Bright chocolate brown *thiastoralis*. with darker lines. The forewing with traces of a subapical line and 5 or 6 transverse lines. The hindwing besides with a dark spot at the cross-vein. Described from Brazil. 16 mm. Specimens from Jamaica and Cuba, according to WARREN, are larger, browner, the forewing more excurved at the distal margin in the middle. Specimens from Ecuador, according to SCHAUS, typical, also those from Panama. Specimens from Costa Rica have also a normal shape of the wings, but they are as large as Cuban specimens.

R. spurcatula *Warr.* (173 g) is somewhat similar to the preceding species, but without metallic scales *spurcatula*. beneath. Ground-colour reddish yellow with black reticular lines. On the forewing they are united into 2 interrupted bands shortly before and behind the middle. Costal margin with small black squares, with brown spots between. More densely arranged black reticular lines at the apex and distal margin. Hindwing with a black basal band and a double row of black spots through the centre. 1 ♂, 19 mm, from Paraguay.

R. punctum *Fldr.* (173 g) is scantily marked. Body and wings pale brown. Forewing somewhat darker *punctum*. near the base, the margin in both wings very pale. Both wings with few black scales, hindwing with a large black central spot. 20 mm. Amazons.

R. guttulosa *Warr.* Body and wings pale reddish ochreous. Forewing darker at the distal margin, the *guttulosa*. costal margin olive with small white spots followed by short white streaks which are then continued from the submedian fold to the inner margin. A dark shadow close before the distal margin. Hindwing traversed by white striation. An interior and exterior white line more distinct, the enclosed median band somewhat green, with fine white dots. 24 mm. Described according to 1 ♀ from Cayenne.

R. carneola *Fldr.* (173 h). Body reddish ochreous, wings whitish. Forewing broadly pale at the costal *carneola*. margin, reddish ochreous, densely covered with parallel undulate lines, somewhat darker brown. Hindwing the same, the costal margin not darkened. 22 mm. Amazons.

R. guttula *Pagst.* (180 h) has been omitted by HAMPSON in his Monography, while WARREN mentions *guttula*. the similar species *Symphleps ochracea* *Pagst.*, but not *guttula* itself. In the wing-contours and the scheme of markings, *guttula* resembles a large *Symphleps suffusa* *Warr.* (Vol. XIV, pl. 75 i, not 76 k) from Africa, as well as *carneola*. Body and wings pale brownish, with a silvery gloss. The silvery spots of the forewing are especially at the costal and inner margins, the distal margin is narrowly dark brown, darker and broader at the apex. No other marking. Hindwing more profusely covered with band-like silvery scales which are only absent on the narrow dark distal margin. ♀ 26 mm. Amazons.

- xanthina*. **R. xanthina** *Fldr.* (173 h). Judging from the figure in the Novara work, t. 134, f. 15, it is quite uncommonly marked for a *Thyridida*, but this is only due to the figure being badly drawn. We are indebted to Dr. JORDAN for supplying us with a sure specimen from Cayenne, which we figure here. The body is reddish ochreous. Both wings yellow. Forewing densely and finely striated reddish ochreous, the most densely in the basal area. A triangular area without striation at the apex, its point reaching down to vein 5. Hindwing reddish ochreous at the inner margin. The streaks darker, somewhat reticular with wide meshes. Uniformly broad dark brown at the distal margin, only the veins remaining yellow. 24—27 mm. Described from the Amazons.
- rhomboidea*. **R. rhomboidea** *Warr.* (= *laevigata* *Pagst.*) (173 h) reminds us of *anastomosalis* by the long abdomen and the similar marking. Body and forewing reddish brown with paler bands. A narrow indistinct interior band bent obliquely inward. The median band as narrow at the inner margin as the interior one, much broader at the costal margin with a blackish brown spot at the costal margin in the middle. A narrow submarginal band, likewise widened at the costal margin and with a spot, obliquely outward as far as vein 7, then narrower, more extinct, parallel with the margin. The light colour predominates somewhat on the hindwing, the dark colour forming the bands, an interior band, a median and a marginal band, very irregular, of a variable extent, a light spot at the apex is mostly cut off. 25—30 mm. Chiriqui, Peru, Amazons.
- changuinola*. **R. changuinola** *Schs.* Thorax dark grey, abdomen pale brown. Forewing pale brown, with a large white median and exterior shadow at the costal margin and a narrower submarginal shadow, the inner margin somewhat grey. The interior line more excurved than the basal line. Median line oblique, excurved above the submedian fold. Exterior line obliquely excurved from the white costal-marginal spot to the inner margin near the anal angle. The submarginal line stronger, from the costal margin to vein 4 at the distal margin. The interior line on the hindwing somewhat angular, the median line fine, a dark spot at the cross-vein. The exterior and submarginal lines distinct, with a feebler line between them. ♂ 15 mm. Costa Rica.
- nubila*. **R. nubila** *Hmps.* Body dark greyish brown, wings dull red-brown. Forewing dark violettish brown at the base and in the marginal area behind the cell, owing to dense striation. Hindwing with such striation especially at the base, behind the cell and at the apex. 1 ♂, 28 mm, from British Guiana.
- aurifera*. **R. aurifera** *Hmps.* (173 h). Thorax red-brown, abdomen darker. The forewing red-brown, grey at the inner margin, the distal margin violettish grey, with numerous blackish reticulated lines. A triangular golden yellow spot from the middle of the costal margin to the lower cell-angle, and a less conspicuous one, slightly tinged with red-brown, from the apical part at the costal margin to vein 5. The first with few reticular lines, the other one with more numerous ones. The hindwing pale red-brown, with more distinct dark reticular lines. ♂ 24 mm. Described from Paraguay. In the Senckenberg Museum 2 ♂♂ from Alto da Serra and Viannapolis. I consider it possible that the species is identical with *amethystea* *Fldr.* (173 g).
- lilacina*. **R. lilacina** *Warr.* Lilac brown. Forewing with a brownish ochreous, dark striated large triangle each at the costal margin before the middle and behind it as far as the apex. Hindwing with a somewhat brownish ochreous median area, the whole rest of the wing lilac. A distinct dark spot at the cross-vein. ♀ 26 mm. Rio de Janeiro.
- quinquelineata*. **R. quinquelineata** *Warr.* (175 f). Body and wings whitish ochreous. Forewing with dense brown reticular lines, partly united into bands. Hindwing with 5 nut-brown lines, parallel with the distal margin, the 3 first being double. The first at the base is short, the second bent, the third broad, ending at the upper edge of the cell. The exterior and submarginal lines are thick, with reticular lines between them. ♂ 34 mm. Described according to a damaged specimen from Bogota. We figure a specimen of the Tring Museum from Cayenne. However similar *quinquelineata* is to the following species, yet it seems to be different from it.
- tristriata*. **R. tristriata** *Pagst.* has already been mentioned in dealing with *Herdonia thetis* (p. 1192). Body and forewing yellowish. Short white horizontal patches at $\frac{2}{5}$, $\frac{1}{2}$ and $\frac{3}{5}$ costal margin; they may also occur in *quinquelineata*. From vein 7 to a little below vein 4 a submarginal oval white spot with undulate vertical yellow lines. The continuation to the inner margin is basally removed by the width of the spot, less sharply edged, different from *quinquelineata*. Narrowly brown behind it. Hindwing somewhat lighter, with 3 bands. The interior one is narrow, straight, not compressed in the middle, the second of *quinquelineata* is absent, the third is angled, not rounded in the anterior part. The next line is absent, the submarginal one is straighter in its anterior part. 1 ♂, 28 mm. Montevideo.
- multifasciata*. **R. multifasciata** *Warr.* (173 h). Creamy white. The forewing with numerous pale ochreous bands, parallel with the distal margin, darker and more distinct below the median vein; the postmedian bands between vein 4 and the submedian fold greyer, forming a somewhat triangular spot. Costal margin paler, the distal margin narrowly brownish ochreous, paler before it. The hindwing with 6 more distinct dark bands, the light interspace also band-like. Apex pale in both wings. ♂ 22 mm. Ecuador.
- colorifera*. **R. colorifera** *Warr.* (173 i). Body greyish green. Forewing ochreous, with a pink tint extending beyond the middle, with fine reticular lines and a few black scales. The basal area with 2 or 3 greyish green bands. A straight black band from $\frac{3}{5}$ costal margin to $\frac{3}{4}$ inner margin, behind it two bent rows of black spots and a dark

spot at the anal angle. Hindwing pink with irregular lines of black dots. The black line of the forewing is continued on the hindwing. ♀ 22 mm. Peru.

R. polychloralis Pagst. (173 h). Wings greyish brown with a violet shine. Forewing with a broad golden brown stripe below the costal margin almost as far as the distal margin. Besides short red-brown transverse stripes laterally edged with black. A basal stripe, an interior and a median stripe, extending to the submedian fold. Behind it two short stripes and one oblique subapical stripe. Hindwing with quite faded stripes, at the base, in the middle and outside. ♂ 26—28 mm. Chiriqui. — *rosenbergi* Warr., from Peru and Ecuador, is identical with *polychloralis*.

R. triangulifera Warr. (173 i). Wings greyish ochreous, with darker brown reticular lines, the marking dull red-brown. Base of forewing greyish ochreous, obliquely cut off. Interior band narrow, bent, nut-brown at the costal margin. Exterior band broad, rectangular, its interior edge from $\frac{2}{3}$ costal margin to the middle of the inner margin, the exterior edge obliquely outward as far as vein 6, then parallel with the interior edge, undulate; this band is nut-brown also in front. Marginal band from near the apex outward, then along the margin, its interior edge ending at the anal angle. All these bands finely striated. The light band of the ground-colour before the exterior band strangulated below the middle and containing some fine hyaline spots there. Hindwing with a red-brown interior, exterior and marginal band with undulating edges, the median area lighter. ♂ 30—35 mm. Rio de Janeiro and Upper Amazon R.

R. anastomosalis Pagst. (173 i). Forewing not particularly narrow, as the author states. Wings lustrous light yellowish brown, with darker brown bands on the forewing and with reticular lines. An indistinct bent interior band and one at the base, quite indiscernible in the type. Exterior band very broad at the costal margin, almost linear in the submedian fold and much darker inside, somewhat widened towards the inner margin. At the costal margin outside a broad light triangle is cut off in the band, the costal margin being narrowly whitish also towards the base between the median and exterior bands. Margin broadly dark, bent inward at the costal margin, besides an oblique subapical line. Hindwing with a feeble median band, shaped exactly like the exterior one on the forewing, enclosing a relatively large hyaline spot in the cell. An irregular dark line from $\frac{3}{4}$ costal margin to the anal angle. Both wings besides with dense reticular lines. ♂ 20—25 mm. Chiriqui, Novo Friburgo, Itatiaya.

R. subtransversalis Warr. (173 i) is said to resemble *anastomosalis*. Forewing pale yellowish brown with fine dark incomplete reticular lines. No bands present. Hindwing more reddish. A faded reddish stripe extends from about $\frac{1}{3}$ inner margin towards the apex of the forewing, not reaching it. 24 mm. 1 ♂ from Central Surinam.

R. rufigrisea Warr. (173 i). Forewing dull brick-red with dense violettish-grey reticular lines leaving free only the costal margin before and behind the middle and a spot below the cell-end. The grey lines are densest at the base, behind the cell and at the distal margin; pale rings between them are mostly grey, some also reddish. Two dark spots at the base of veins 4, 5 and 6. On the hindwing the colours are exchanged. The anal angle dull red, the rest greyish violet with feeble red lines. 24 mm. 1 ♂ from Venezuela.

R. curvistriga Warr. (174 a). Reddish yellow with dark brown reticular lines. Forewing with a square at the middle of the costal margin, bordered by the dark reticular lines, filled with brown, from its lower exterior angle a bent brown line extends to the apex. A dark subapical line cuts off a triangle at the apex. A fold in the cell and behind it. Hindwing with brown reticular lines without bands. The fold is less strong. ♀ 24 mm. Surinam, Cayenne.

R. rufidorsata Warr. (173 i). Chocolate brown. Forewing reddish at the costal margin, with vertical pale lines. The basal and interior lines parallel, somewhat inward, the exterior one running to the anal angle. Submarginal line from the costal margin to the distal margin below the middle. Finer lines between them. Hindwing with an interior and exterior line, besides finer ones. The marking is very indistinct in both wings. 1 ♂, 20 mm, from Surinam.

R. molecula Dyar. Creamy white. Forewing with fine grey lines. In the interior third of the wing there is a grey round spot in the middle, an irregular band in the exterior third, broader at the costal margin. A red-brown subapical band to vein 5 at the margin, forked below, and a short band at the anal angle. Hindwing with a narrow grey interior band, the median band broad, extending in front as far as vein 7, narrower at the inner margin, grey. The submarginal band narrow, red-brown in front. 20 mm. Panama.

R. neapolitana Warr. Forewing creamy white, with ochreous flesh-coloured strigae. Costal margin spotted light and dark. 4 or 5 indistinct rows of dark spots, interrupted; only the submarginal band is entire, with dark horizontal streaks above the middle, ending in white spots outside. The exterior band between veins 5 and 1 greenish, spindle-shaped, edged with white. Hindwing whitish, with 6 parallel dark bands, the two middle ones of which are green. 1 ♂, 17 mm. Surinam.

R. violalis Pagst. (173 i). Ground-colour pale reddish brown, tinged with violet. Forewing with numerous fine dark brown reticular lines, streaks and dots. Some specimens show 2 or 3 parallel lines, vertical above the inner margin, bent round towards the base before the costal margin. The darker margin is narrow, black dots in the marginal area. Hindwing paler at the base, with numerous blackish dots. 14—21 mm. Mexico,

arcuata. Costa Rica. Ecuador, Bolivia, Rio de Janeiro. — *arcuata* Pagst., from Chiriqui, which was not at hand, may be only a more distinctly marked *violalis*, in which the striation of *violalis* is united into interrupted lines.

The following species, detached by WARREN as the genus *Siculodes* Gn., are all more or less white, the marking consists of dark lines, more rarely of dark spots. The antennae are long.

pulchelloides. **R. pulchelloides** Pagst. (174 a). White, lustrous, the hindwing somewhat diaphanous, more opalescent than the forewing. The latter with numerous rows of pale violettish brown dots in the basal area and in the centre, larger spots near the anal angle, variably shaped in the individual specimens, few fine streaks in the apical area. Hindwing with small spots only at the margin, without any other marking. 24—30 mm. Panama, Colombia, Peru, Brazil.

triumphans. **R. triumphans** Warr. (174 a) is much larger than *pulchelloides*, distinguished by a pink marginal line and yellow fringe. Very similar to *pudicula* Gn. from the Indo-Australian Region. Ground-colour silky white. Forewing olive grey at the costal margin, striated dull reddish brown, with 4 oblique oblong red-brown spots at the apex. Basal half with black lines, fused into a spot below the middle of the wing. An oblique black band before the middle of the inner margin, somewhat reddish below the costal margin, divided between the veins by yellowish white horizontal streaks, and with a large white spot behind the cell, almost interrupting them. A black band at $\frac{3}{4}$ inner margin extends to vein 4. Black spots at the anal angle, forming a divided band above vein 2, which reaches vein 6. Marginal area pink. Hindwing with irregular olive brown streaks at the base, a round dark spot at the anal angle, 6 black submarginal spots. 1 ♀, 50 mm. Peru.

perlula. **R. perlula** Gn. (174a, b). Both wings strongly iridescent, sometimes the costal margin of the forewing somewhat brownish. The brownish reticular lines of the forewing mostly with rather wide meshes. The lines of the hindwing are not so reticular, only irregular. Forewing beneath often red-brown in the basal and median areas in front, as well as at the costal margin, mostly quite lustrous silvery without any red-brown marking, and even if a brown subapical line is present, the silvery lustre from the apex extends yet beyond it. 26—30 mm. Peru, Bolivia, Brazil, Cayenne.

paullula. **R. paullula** Pagst. (174 b) is mostly much smaller than *perlula*. The wings are white. Forewing with many tiny brown streaks which are more densely arranged at the middle of the inner margin and form part of a median band. The streaks on the hindwing rather form lines. The ♀ is larger, especially the forewing somewhat brown, tinged with violet. The basal area and a median band widening anteriorly are darker, but all the borders faded. Hindwing as in the ♂, slightly browner. Forewing beneath with a sharply cut off silvery apical triangle, vein 7 remarkably red. 17—26 mm. Guatemala, Chiriqui, Peru.

sterna. **R. sterna** Fldr. (= *virginula* Gn.) (180 g). Wings purely white only in the external parts, the rest pearl-coloured, with numerous black streaks inclined to form lines. No distinct bands recognizable. Forewing beneath yellowish, the veins also yellow, only close at the margin they turn red. 34—40 mm. Bogota.

intermedia. **R. intermedia** Warr. (174 b) is in size between the two similar species *paullula* and *sterna*. Remarkably separated from them beneath. On the forewing of *intermedia* all the veins are uniformly pink. Two faded reddish yellow spots in the submedian fold and one at the distal margin. In *sterna* the spots are hardly visible, in *paullula* they are dark red-brown. 26—30 mm. 3 ♂♂ from Peru.

figurata. **R. figurata** Warr. (174 b). Forewing chalky white with light and dark brown reticular lines, the costal margin bronze brown at the base, from where brown double lines proceed. The reticular lines before the distal margin between the veins 4 and 7 are filled with brown and form an oblong spot. Hindwing paler, with fine red-brown reticular lines. Both wings beneath with thicker, reddish grey streaks. Black metallic scales in the cell and at veins 8 and 9, and a pale red-brown streak below the costal margin. 22—30 mm. Peru.

rufifimbria. **R. rufifimbria** Warr. (174 c) is somewhat similar to *figurata*. Forewing chalky white, with numerous brown reticular lines, darkest at the inner margin. A brown streak at the cross-vein. Costal margin pale reddish yellow, darkest at the base. Regular brown streaks at the costal margin. Hindwing similar, but white at the costal margin, with thick transverse lines. Forewing beneath with black metallic scales at the base and upper cell-end, besides a red subcostal streak and a similar spot below the cell-end. ♀ 30 mm. Panama.

stigmatophora. **R. stigmatophora** Warr. (174 a). White. Forewing with numerous grey reticular lines, with a slight grey tinge in the interior two thirds, proceeding from 6 pairs of dark grey lines at the costal margin, 3 each before and behind the middle. A large black spot at the cross-vein. The reticular lines at the distal margin with wider meshes, browner, separated from the others by a white, scarcely marked submarginal band. Hindwing with a grey median band of 3 or 4 reticular lines, enclosing a black cellular spot, a white band before it and 2 blackish basal lines. The marginal area as on the forewing. 44 mm. 1 ♀ from Peru.

sublivescens. **R. sublivescens** Warr. (174 c) resembles a better marked *lacteguttata*. Wings hyaline white, opalescent. Forewing uniformly covered with olive brown reticular lines, broadly greyish brown at the costal margin, reddish

bronze towards the apex. An oblique dark line at the cross-vein. Hindwing the same, but without a dark costal margin. Costal margin of forewing beneath broadly, of hindwing narrowly olive bronze. The ♀ more opalescent. Forewing with 8 or 9 reddish bronze spots at the costal margin. Two reddish olive spots at vein 1 and a similar submarginal one behind the cell. 45—50 mm. Described according to a couple from Peru.

R. lacteguttata Warr. (174 c). White, semidiaphanous, opalescent, with numerous greyish green reticular *lacteguttata*. lines, so that the ground-colour is reduced to round white patches. The larger spots at the veins form an exterior band, the submarginal row consists of smaller round spots. Costal margin dark iron grey with white spots. Hindwing similar, but lighter. 45 mm. 1 ♀ from Peru.

R. ferrugata Warr. (174 c). Creamy white. Forewing with irregular branched brown strigae and dark *ferrugata*. rusty red reticular lines. The costal margin dark brown at the base, with dark brown strigae behind it. A straight brown line extends from the middle of the inner margin obliquely upward to the upper cell-angle, from there inward to the middle of the costal margin. United at the bend with a line from the costal margin to the anal angle. Two widely ramified lines in the interior half from the costal margin, the third of them divides the straight oblique line below the middle. Three ramified finer lines near the apex. Hindwing with a strong brown median line, with 2 or 3 more lines behind it, stronger only near the anal angle. Forewing beneath with an orange subcostal streak, black metallic scales at the upper cell-edge. ♂ 28 mm. Peru.

R. ferreiceps Hmps. Body brownish, wings silvery white. Forewing strongly tinged with brown, the *ferreiceps*. median area with undulate brown lines, the marginal area with a few black streaks, the costal margin dark iron brown at the base, predominantly white behind it. Hindwing with brown reticular lines and brown veins. Somewhat reddish yellow at the base, the median band brown, enclosing white spots, excurved around the cell. The margin reddish brown except at the apex. Forewing beneath fiery red-brown in the cell and its surroundings. A triangular fiery brown spot below the cell-end, a square black spot above the anal angle. 1 ♀, 40 mm. Guiana.

R. viriditincta Warr. (174 b). White, not hyaline or opalescent, the dull olive brown reticular lines *viriditincta*. rather thick. The median vein and veins 1—4 on the forewing dark olive brown, and a similar streak below the costal margin. The costal margin with distinct olive brown streaks. A dark spot at the cross-vein, similar spots at the ends of the veins. An olive brown oblique spot above the middle of the inner margin. All the lines of the hindwing are almost parallel with the distal margin, fewer lines at the base. Beneath slightly tinged with olive. Black and yellow streaks in the base of the cell, also at its upper edge towards the end. ♀ 45 mm. Ecuador.

R. postponens Dyar. Whitish. The marginal half of the forewing tinged with violet, numerous blackish *postponens*. grey lines, the 5 interior ones interrupted, the 4 exterior ones more continuous, bent. A red shadow behind the cell-end, a black spot below it. A white spot with a black dot at the apex. Hindwing whitish in the interior area, violettish grey at the apex, median band grey, blackish violet inside. 23—26 mm. Panama.

R. roseobrunnea Warr. (174 c). White with a violet shine. Forewing with numerous pink and brown *roseobrunnea*. lines proceeding from olive brown spots at the costal margin. The lines are more densely arranged in the median and marginal areas, separated by a lighter area. Hindwing with more equably distributed pink lines, somewhat thicker at the inner margin, the costal margin pale. Forewing beneath olive brown, without lines, hindwing lighter than above, with pink lines. 24—28 mm. Peru, Bolivia.

13. Genus: **Zeuzerodes** Pagst.

Chiefly separated from *Rhodoneura* by the shape of the wings. Forewing very oblong, the costal margin bent before the apex, distal margin very oblique. Hindwing relatively still more oblong, with a very pointed apex, somewhat prominent in the ♂ at the anal angle. The genus is represented only in South America. Type: *leuconotula* Pagst.

Z. leuconotula Pagst. is very similar to *Meskea dyspteraria* (175 h). Body dark wood-coloured brown. *leuconotula*. Forewing yellowish brown, darker brown through the cell towards the apex, lightest in the submedian fold in the basal part. A white dot at the costal margin close before the apex, a white, black-centred spot at the distal margin close below the apex. Black spots chiefly radially accumulated in the median area. Hindwing much darker brown, lighter only at the apex. A broad white spot extends from the anal angle for some distance along the margin, then forming a long point towards $\frac{3}{4}$ costal margin, the anal angle itself somewhat yellowish. 40 mm. Chiriqui.

Z. fumatalis Pagst. (174 d). Dark violettish brown. Forewing with indistinct light round spots with *fumatalis*. a dark central dot. These spots are most distinct in the centre of the wing and at the anal angle. Hindwing horizontally divided from the middle of the inner margin. In front coloured like the forewing, darkest at the border-line, yellowish white at the anal angle, purely white towards the border and undulate. Forewing beneath with an indistinctly yellowish apex and a black double dot at the apex. 30—36 mm. Chiriqui, Brazil.

- nigrata*. **Z. nigrata** Warr. (174 d) is somewhat lighter than *fumatilis*. Forewing dark smoky brown, ochreous only at the inner margin behind the middle, enclosing two short oblique dark stripes, the interior one broad, the other one narrower. In a specimen at hand from the Tring Museum, the forewing is uniformly parallel striated dark. Hindwing the same. The anal triangle whitish with a brownish ochreous line. Described as *Meskea*. 32—40 mm. Amazons, Cayenne, Colombia.
- castanea*. **Z. castanea** Warr. (174 e). Forewing flesh-coloured ochreous, somewhat rusty brown. Costal margin broadly violet, narrower violet at the distal margin, the inner margin dark brown. A dark brown spot in the middle of the cell, a larger one behind it. From its inner side a long bent streak extends to the apex below the costal margin. The spot is connected outside with the distal margin between veins 3 and 4 by a violet shadow, a brown band extending from its inner side to $\frac{3}{4}$ inner margin. Hindwing rusty brown with few brown reticular lines, violettish brown at the apex and margin. ♀ 38 mm. Peru, Colombia. — **caenosa** Dgn. Forewing earth-brown, the lines dark brown, especially at the costal and distal margins. A large brown spot at the cell-end and behind it. A submarginal row of 4 brown streaks behind it, the upper ones penetrating into the dark marginal band. Besides there are brown dots replacing an interior, a median and an exterior line. Hindwing also with rows of dark dots forming faded lines at the anal angle, the distal margin dark. ♀ 36 mm. Cayenne.
- maculata*. **Z. maculata** Warr. (174 d). Forewing black, iron grey at the costal margin with dull red-brown scales. Whitish, grey-centred spots in the cell and behind it. A large white spot in the submedian fold before the margin. Fine grey lines at the apex. Hindwing greyish black in the anterior half, the anal triangle creamy white with two reddish yellow pale undulating lines. ♀ 36 mm. Peru and São Paulo. Presumably a form of *fumatilis*. It chiefly differs in the distinct edges of the white spot in the submedian fold of the forewing.
- fasciata*. **Z. fasciata** Warr. (174 d) is brownish ochreous with darker brown streaks. The latter are arranged band-like on the forewing, parallel with the distal margin, those at the margin itself being broader, more distinct, darkest at the anal angle, lighter at the apex and bent over to the costal margin. Before them there is a distinct light band and before this a dark median band, broader at the costal margin, extra-angular behind the cell. 3 or 4 indistinct dark bands at the base, a black blotch in the cell. Apex whitish. The brown median and marginal bands of the hindwing very distinct, the light interspaces with reticular lines. Not white at the anal angle. ♀ 40 mm. Peru.
- The following species of which only the ♀ is known differs somewhat in the shape of the hindwing. An obtuse projection is at the apex, the distal margin projecting below the middle in a broad pointed dent, the inner margin is rather short, ending in a small lobe.
- argentistriata*. **Z. argentistriata** Warr. Pale wood-brown, somewhat reddish. The costal and distal margins of the forewing paler, brownish ochreous, with scanty black scales. The redder part of the forewing with irregular black streaks. A dark cloud from the middle of the inner margin to the space behind the cell. A light, black-centred spot at the apex. Hindwing with a darker marking forming a blackish median band which is angled outside. Apical area dark. A fine red-brown streak at the middle of the distal margin. 1 ♀, 30 mm, from Venezuela.
- subfulvata*. **Z. subfulvata** Warr. (174 d). In the author's opinion the species is similar to *Loxiorhiza cervinalis* and *Zeuserodes nigrata*, so that it may not belong to this genus. Greyish ochreous. Forewing densely striated dark brown, without any recognizable marking. Hindwing similar, with traces of an exterior band of 3 or 4 dark lines. Costal margin of forewing inserted in the middle, the distal margin of the hindwing straight. 40 mm. 1 ♀ from Ecuador.

14. Genus: **Loxiorhiza** Warr.

Wings shaped like those of *Zeuserodes*. Costal margin of forewing slightly inserted in the middle, the distal margin very oblique, the anal angle very much rounded. The inner margin of the triangular hindwing is very short. Veins 4 and 5 of the forewing above the lower cell-angle, 6—9 close together at the upper angle. Only 1 species.

- cervinalis*. **L. cervinalis** Pagst. (180 h). Forewing pale reddish brown, covered with dark dots and streaks, not forming distinct lines. Hindwing the same, broadly darker red-brown at the anal angle. Paler beneath, the cross-vein prominently black in both wings. The striation is as insignificant as above. 28—38 mm. Peru, Brazil.

15. Genus: **Macropota** Warr.

Forewing long and narrow, straight at the costal margin, bent before the apex. Hindwing undulated at the margin, apex obtuse, with a dent at vein 7, cut out below it, the inner margin short. Only one species described as *Siculodes*.

- eupithecula*. **M. eupithecula** Gn. (*eupitheciata* Warr.). Wings lustrous greyish yellow, strewn with black scales, without any other marking. Beneath at the apex of the forewing there is a white spot with a black dot. The veins with silvery blue scales. 23 mm. Cayenne.

16. Genus: **Rhodogonia** Warr.

Forewing straight at the costal margin, bent before the apex, apex pointed, distal margin with a small dent at vein 7, excurved at vein 4, oblique below it. Hindwing with a round apex, the margin angled at vein 4. Palpi erect, long. Neuration as in *Rhodoneura*. The first species, *miniata*, is only known as ♀, the other species, *subfusca*, was described from a ♂. WARREN, however, is convinced that they are two different species.

R. miniata Warr. (173 d). Wings yellowish ochreous with dense red reticular lines and a few dark brown *miniata* spots, a larger one of which behind the cell is more prominent on both wings. The specimen figured, however, is red with fine dark striation. On the hindwing a brown shadow extends from this spot to the inner margin. Forewing beneath with traces of a median band which, however, is absent in the specimen figured. ♀ 36 mm. British Guiana.

R. subfusca Warr. Reddish yellow with an olive brown shine, striated dark between the veins. Red *subfusca* scales at the base and in the costal-marginal area. The costal margin itself snow white with 5 red dots in the basal half and 2 red blotches in the distal half, reddish brown at the apex. A dark spot at the cell-end. The fringe in the incurvations snow-white. Hindwing somewhat brick-red at the base, the distal half tinged with olive brown. A dark shadow from the cell-end to the inner margin. The costal and inner margins somewhat yellowish. Beneath dark olive brown, more brownish ochreous on the hindwing. The inner margin broadly whitish on both wings. ♂ 35 mm. Cayenne.

17. Genus: **Hexeris** Grt.

Beside *Risama Wkr.*, this is the only Thyridid gems in which the long palpi project horizontally. Antennae of ♂ feebly serrate. Forewing with a slightly inserted costal margin, the distal margin slightly excurved at vein 3, all the veins free. Hindwing likewise somewhat excurved at vein 3. The genus contains but one species.

H. enhydria Grt. (= *reticulina* Beut.) (174 e). The determination of the genus has caused great difficulties *enhydria* to the two authors, and GROTE fully describes the origin of the frenulum, but he does not mention anything about the family to which he would like to have his new genus placed, except the remark that it is very similar to the *Geometridae*. The wings are pale cinnamon brown with numerous dark reticular lines. Among them a median line on the forewing is more conspicuous, despatching a branch from the lower cell-angle to the costal margin towards the base. It is continued on the hindwing to the middle of the inner margin, a feebler branch extends from its apex at the costal margin dentately to the anal angle. 25—33 mm. A few species known from Florida, also from California.

In the following genera the forewing is more or less distorted, sometimes also the hindwing.

18. Genus: **Hepialodes** Gn.

Palpi short, porrect. Forewing inserted at the middle of the costal margin, irregularly cut off at the apex. Distal margin bent. Hindwing with 2 excisions at the costal margin near the apex. Neuration as in *Rhodoneura*. Only 1 species.

H. follicula Gn. (174 e). Reddish brown, more or less tinged with violet, the intensity and number of *follicula* the dark reticular lines being also variable. Forewing with a straight somewhat oblique median line, slightly forked at the costal margin. The cross-vein on the hindwing is distinguished by a fine silvery line, traversed by the dark somewhat bent median line. The reticular lines are just as variable as on the forewing. 55—75 mm. Guiana, Brazil.

19. Genus: **Belonoptera** H.-Schöff.

Both wings with a more or less pointed apex, the distal margin below it cut out. Type: *phyllula* Gn. The species differ from one another in the shape of the wings and the marking as much as the species of *Draconia* do. The two genera might be united.

We begin with the two species in which the distal margin is rather much notched in both wings, as in the *Draconia*-species.

B. nervicula Gn. (174 f). Ground-colour dark yellow with fine red-brown reticular lines none of which *nervicula* is particularly prominent in my only specimen; there are only traces of one somewhat darker small triangle each marked by bifurcation at the inner margin, before and behind the middle. The lines which are rather fine everywhere are somewhat more densely arranged in the basal third. Hindwing with somewhat more prominent interior, median and submarginal lines. At the median line there is a large white spot in somewhat darker surroundings at the cross-vein. Distal margin notched at the veins in both wings. Anal angle of forewing projecting far. Hindwing with a long apex at vein 7, another angle at vein 8, which is not so very prominent in the specimen figured from the Senckenberg Museum. The transverse lines are strong on both wings in this specimen. ♂ 62 mm. Peru, Brazil.

cancellata. **B. cancellata** Warr. (175 f). The shape of the wings is not described by the author; judging from a specimen kindly placed at our disposal by Dr. JORDAN, it resembles *nervicula*, but the denticulation is stronger on both wings. Wings brownish ochreous. Forewing with a blackish brown stripe below the costal margin proceeding from the base, broader outside, extending into the apex. Dark streaks at the costal margin, larger spots before the apex. The wing is traversed by 9 parallel vertical brown lines at equal distances, only the seventh line being somewhat more bent. Besides fine brown reticular lines. A white streak at the margin above vein 7. Hindwing with 5 parallel lines in the basal half and a very much ramified one from $\frac{1}{2}$ costal margin. 1 ♀, 50 mm. Peru.

In the following species the apex is very pointed in both wings, the distal margin not or hardly notched. The anal angle of the forewing is angled, but not projecting. Hindwing without an angle at vein 8, faint traces of it only in *phyllula*.

phyllula. **B. phyllula** Gn. (174 e ♀, f ♂). Wings somewhat more oblong and somewhat lighter than in *nervicula*. The fine and stronger lines are just as irregular. A straight median line on both wings may be worth mentioning at most. This species also shows the conspicuous white spot on the hindwing, which HERRICH-SCHÄFFER has omitted on his figure 403. The resemblance of *phyllula* and *nervicula* is considerable, yet they are probably different species. A tiny specimen with an expanse of 38 mm is before me from the Senckenberg Museum. 55—60 mm. Brazil.

patercula. **B. patercula** Pagst. (174 g). Ground-colour pale yellowish, somewhat diaphanous, the marking red-brown. Costal margin of forewing red-brown as far as the apex, a subapical band terminates at the margin at vein 4. The median band from $\frac{3}{5}$ costal margin to the middle of the inner margin, where it widens and encloses light dots. A large irregular spot in the middle of the marginal area above vein 2, with a side-branch extending to the anal angle. Hindwing with an equably broad median band enclosing a white dot at the cross-vein. A large square spot at the costal margin near the apex, a just as large anvil-shaped spot between veins 2 and 4. Besides both wings are densely covered with red-brown reticular lines. The description refers to the type. All the other specimens which I saw are less intensely marked, so also the specimen from the Senckenberg Museum, which we figure. In most of the specimens the median bands are only median lines; the same is the case with the subapical line. The last spot on the hindwing is almost invariably absent. A tiny specimen of 30 mm is before me from the Senckenberg Museum. 45—55 mm. Brazil. — **fratercula** Pagst. (174 f), according to the description, might be a very feebly marked *patercula*. We figure such a specimen from Blumenau in the Senckenberg Museum. The habitat stated to be California is improbable. ♂ 42 mm.

arachnidia. **B. arachnidia** Warr. (174 g). Pale greyish yellow, with dense dark reticular lines, the lines and shadows red-brown. Forewing darker at the base, bordered by an irregular bent line. The median line is just as irregular. The exterior line from $\frac{2}{3}$ costal margin to the middle of the inner margin, oblique, thick, forked at the costal margin, with a red-brown shadow behind it, which is narrow in front and reaches the margin at vein 2. A black streak below the costal margin in the last quarter to the apex, from its beginning a red-brown stripe extends to the margin at vein 4. Hindwing with a long light streak at the cross-vein, fadedly darker behind it. Darker also at the apex. ♀ 68 mm. Peru.

sanguinea. **B. sanguinea** Warr. (175 a) shows the apex of the forewing very much produced, but the apex of the hindwing broadly cut off. As it is somewhat similar to the following *frondicula* Gn., we place it here, although *Drac. peripheta* is still more similar. Forewing brownish ochreous, diaphanous, the marking dark red-brown, hemochrome at the distal margin between veins 2 and 5. The inner margin dark red at the base as far as the submedian fold, where it meets a band proceeding from the median vein at the base of vein 2. A broader oblique band from the middle of the inner margin to the cell-end encloses a round pale spot. Both the bands are branched towards the costal margin, prolonged to the apex as a costal stripe, containing a few pale spots. A few oblique lines at the apex. A red-brown spot at the anal angle, pointed above, extending to vein 4. Before this spot two more as far as the median band and some above vein 5. The whole wing with reticular lines. Hindwing dark red. Paler near the base before the broad interior band, a larger light spot at the costal margin behind the middle, a smaller one behind it, two at the anal angle. ♀ 60 mm. Cayenne, Amazons.

frondicula. **B. frondicula** Gn. (= *matricula* Gn.) (174 g). In both wings the apex does not project quite so much as in the preceding species. Ground-colour reddish yellow, somewhat diaphanous. Forewing red-brown at the base. As the beginning of the interior line there is a spot at the costal margin. Median band broad, divided at the costal margin, bent somewhat basad. A spot at the anal angle may be connected by irregular lines with the median band at vein 3. A triangular preapical spot the lower point of which is prolonged to a subapical line or row of spots. The costal margin is not throughout red-brown, by what it is well discernible from *patercula*. Hindwing with a basal and median band, the latter enclosing a white central dot. An irregular spot at the apex, interrupted and irregularly prolonged towards the anal angle. Besides the red-brown bands there are dense fine reticular lines on both wings, here and there blackish, the others red-brown. 55—70 mm. Brazil.

B. reticula Gn. (= *mediovincta* Warr.) (174 f). Placed to *Risama* by HAMPSON, but probably better *reticula*. ranged here. Forewing as pointed at the apex as in *frondicula*, hindwing pointed at the apex, but not projecting. Ground-colour yellowish hyaline with a red-brown marking. Costal margin of forewing somewhat paler red-brown. The interior band vertical, ending at vein 1. The median band very broad at the costal margin, very narrow from vein 3, somewhat outward as far as vein 1, containing a round spot of the ground-colour above it and widened. A dark reticular line from the anal angle upward almost to vein 4. The red-brown colouring at the costal margin gets narrower towards the apex. Hindwing with dense reticular lines at the margin and the same from $\frac{2}{3}$ inner margin to the cross-vein. 55–60 mm. Brazil. — **mediovincta** Warr. (175 e) differs *mediovincta*. very slightly in the reticulation, the margin of the hindwing is quite linear, as if it were cut off with scissors. It does not deserve a special denomination.

B. purpureofasciata sp. n. (175 a) has more stretched wings. The distal margin of the forewing with the pointed apex and the angle at vein 3 resembles the following species, but the margin is very oblique below *purpurco-fasciata*. vein 3, and the hindwing is much more pointed at the apex. The marking is somewhat similar to *selenioides*. The body is dark pink. Forewing yellow, densely covered with reddish brown little strokes. The transverse bands dark violet. A short vertical band from the costal margin to the base of vein 2. A band from the middle of the inner margin to $\frac{2}{3}$ costal margin, much broader from vein 3 and extended from the middle of the costal margin almost to the apex. From its exterior point a straight submarginal band extends to vein 2, where it is indistinct and broader. Hindwing with a double interior line. Median band extra-angular between veins 4 and 5, broader above it, straight below it to behind the middle of the inner margin. Hindwing with fine dark streaks, somewhat reticular. Ground-colour beneath lighter, the marking distinct. ♂ 45 mm. Type in the Senckenberg Museum (Frankfort on the Maine).

The two following species exhibit a rounded apex on the hindwing. The marking is somewhat variegated.

B. selenioides Pagst. (175 a). Wings yellow in the distal halves. Forewing olive brown in the basal *selenioides*. area. The median band very broad at the costal margin, occupying almost $\frac{1}{3}$ the length of the costal margin. Its distal margin uniformly bent from $\frac{3}{4}$ costal margin to the middle of the inner margin, the interior edge outward as far as the base of vein 3, then inward parallel and close at the exterior edge; the band is darker in its lower part. The costal margin is spotted greyish white as far as the end of the median band. From its exterior angle a subapical band extends to vein 3 and a fine line to the anal angle. Hindwing with a broad olive brown median band, somewhat broader at the costal margin. A line from its angle to vein 3 at the margin, where the latter is somewhat excurved. 40 mm. 2 ♀♀ from the Chanchamayo.

B. excessiva sp. n. (175 a). Costal margin of forewing more undulated than in *selenioides*, somewhat *excessiva*. more projecting at the middle of the distal margin, but uniformly bent at the distal margin of the hindwing. Body and base of forewing somewhat red-brown. Wings brownish ochreous, the marking red-brown. The median band of the forewing shaped like that of *selenioides*. A triangle close behind it at the costal margin as far as the apex from which, below at vein 6, two lines proceed, ending at vein 3 and at the anal angle. Besides numerous finer parallel lines. The median band is continued on the hindwing in the same width. Also here numerous parallel lines. The same beneath. ♀ 22 mm. Rio de Janeiro. Type in the Senckenberg Museum.

20. Genus: **Risama** Wkr.

Palpi horizontally porrect. Forewing very deformed in the typical species and the following one. widely excurved behind the base at the costal margin, inserted in the middle of the costal margin, the apex projecting pointedly, the distal margin cut out above the anal angle. In the other species the anal angle is not cut out, the apex projects much like a sickle. No veins stalked on the forewing. Veins 6 + 7 of the hindwing on a short stalk. Type: *picta* Wkr.

R. picta Wkr. (= *aurorula* Gn.) (175 b). Forewing pink in the convexity at the base of the costal margin, *picta*. moreover in a triangle from the base of vein 2 along the latter and the distal margin almost to the apex, the rest glaringly light yellow. Dark brown circles, forming a band near the base, two of them replacing an interior line, a ring above the middle of the inner margin. small spots at $\frac{3}{4}$ costal margin and at the excision of the anal angle. Hindwing light yellow at the base. Median band broad, brown, with yellow dots, enclosing a large round hyaline spot. The inner margin behind it broadly yellow, the distal margin narrowly brown at the anal end, the rest of the wing pink. 40–44 mm. Brazil.

R. satellifera sp. n. (175 b). Costal margin of forewing less convex at the base, but the anal angle still *satellifera*. cut out. Ground-colour brownish pink. Forewing densely covered with rows of dark brown streaks, somewhat darker at the anal angle. A dark brown short double streak extending obliquely outward from $\frac{3}{4}$ costal margin is the only marking on the forewing. The striation on the hindwing is somewhat less distinct in the marginal area, somewhat darker only at the anal angle. Median band similar to that of *picta*, marked only like a shadow. The hyaline spot as in *picta*, close beside it towards the anal angle 3 small accessory spots. Beneath similar to *picta*, except the absence of the yellow colouring. The median band extends farther in front on the forewing, it is broad and distinct on the hindwing. 36–38 mm. Minas Geraes, type in the Senckenberg Museum, taken by Prof. SEITZ in March 1930.

straminula.

R. straminula *Pagst.* The author was doubtful as to the position of this species; DALLA TORRE placed it here later on. Both wings dingy straw-coloured, with numerous dark transverse stripes extending parallel and almost vertically and being connected reticularly. Costal margin of forewing whitish, a dark brown oblique line before the apex. The dark stripes are continued on the hindwing. 33 mm. Described according to a damaged specimen from Brazil.

The following species have no excision at the anal angle of the forewing.

transversa.

R. transversa *Wkr.* (175 c). Pale greyish brown, with few dark scales. Traces of the beginning of an obliquely outward band at the middle of the costal margin. A radial row of 3 black dots at the apex. Two similar ones at the anal angle and a few more indicated above them. Hindwing with a somewhat oblong hyaline spot, surrounded by a somewhat darker median band. Beneath similar to the two preceding species. 46 mm. Brazil.

eurymenana.

R. eurymenana *Wkr.* (= *subchalybea* *Wkr.*) (175 c). Reddish brown, lustrous, with few dark little strokes. Forewing with a very indistinctly marked median band, extra-angular below the costal margin, then straight, somewhat inward. A narrow band from the apex very obliquely inward, then steeper, from vein 2 vertically to $\frac{3}{4}$ inner margin. Hindwing only with a small hyaline spot at the middle of the cross-vein, without any other marking. Under surface lighter. Basal area of forewing only with a few dark rings. The median line and the line from the apex more distinct, the space between below the cell filled darker, darker also at the anal angle. Hindwing with traces of a broad dark median band. Described according to two specimens in the Berlin Museum, which were thus labelled. 32—40 mm. Brazil.

falcata.

R. falcata *Fldr.* (= *serpula* *Gn.*) (175 e). Dark pinkish brown. The forewing lighter at the costal margin. A somewhat darker interior band from $\frac{1}{3}$ inner margin vertically to the base of vein 2. A band from the apex obliquely to the middle of the inner margin, divided near vein 4 and despatching a branch to $\frac{3}{4}$ inner margin. A darkening also vertical on the anal angle. One large black spot each in the centre of the cell and at the cell-end. Hindwing with a hyaline spot at the cross-vein, an indistinct band before and behind it as on the forewing. Blackish spots near the anal angle. Forewing beneath with but few dark streaks, the apical band more distinct. Hindwing uniformly dotted darker. 34—60 mm. Brazil.

substrigata.

R. substrigata *Wkr.* (175 c). Forewing pale pinkish ochreous, densely dusted dark brown, especially near the inner margin, the dusting at the distal margin united into indistinct parallel lines. A somewhat more distinct line from the middle of the inner margin, forked at vein 2, vanishing at vein 6, continued with 2 blackish spots at vein 8 and below it, and with a dark blotch to the apex. Besides two submarginal rows of brown spots. Hindwing darker, intensely spotted brown, without a hyaline spot, with 3 transverse bands which are only distinct at the inner margin, especially the interior one. Paler beneath. On the hindwing a band and the spots are distinct. On the forewing the band does not extend beyond vein 2 in front. According to WARREN, the specimen denoted by PAGENSTECHER as *falcata* from Massanary and the specimen denoted as *serpula* belong to this place here. As the latter is too much damaged, we figure the former indistinctly marked specimen. 56 mm. Described according to 1 ♀ from Costa Rica.

avicula.

R. avicula *Gn.* (= *macropterana* *Drc.*) (175 d). Judging from DRUCE's figure, (the older) *avicula* differs but little from *substrigata* *Warr.* The colour is almost the same. The band on the forewing extends straightly from the middle of the inner margin to the apex, where it is darkest, without the least trace of a bifurcation near the inner margin. A dark spot is traceable below the middle of the costal margin, and a few submarginal spots near the anal angle. The median band on the hindwing is rather somewhat darker than on the forewing, a few dark rings above the anal angle. The hyaline spot is also absent here. Marking beneath as above, the bands paler. 45—55 mm, Brazil. Costa Rica.

21. Genus: **Vadata** *Wkr.*

Similar to *Risama picta* by the distorted shape of the wings. The forewing, however, shows veins 9 + 10 stalked. The palpi which are rather long in *Risama*, are shorter here than usual. Only 1 species.

macropterana.

V. macropterana *Wkr.* (*maculata* *Pagst.*) (175 c) is uniformly lustrous brown with a violet reflection. Both wings covered with yellow dots. Only the forewing lacks them at the costal margin as far as below the cell. 35—40 mm. Brazil.

22. Genus: **Draconia** *Hbn.*

The wings are more or less angular and notched in all the species, though in very different degrees in the single species. All the veins of the forewing free. Veins 6 and 7 of the hindwing from the upper cell-angle. Separated from *Belonoptera* by somewhat shorter palpi. In the Senckenberg Museum at Frankfurt on the Maine there is a large specimen of *peripheta* preserved in its natural position of repose, as it is described in CRAMER's Work (Vol. II, p. 54). The forewings are flat, but lowered, and the costal margin of the hindwing projects far beyond the costa of the forewing. Type: *peripheta* *Cram.* Excepting *denticulata*, all the species seem to be rare.

I. Hindwing without an excision at the apex, the distal margin rather uniformly notched. Both wings with two points at the apex.

D. denticulata *Pagst.* (175 g). The forewing somewhat extra-angular at veins 3 and 4, with 2 excisions *denticulata*. at the anal angle. Ground-colour yellow, the marking red-brown, of a variable extent, dull. Forewing mostly with a narrow interior band, the median band very broad in front, often extinct between the middle of the cell and vein 2, then narrowly to the inner margin. Submarginal band very narrow in the middle, broadly triangular at the costal and inner margins. Besides numerous fine reticular lines. Hindwing only with a rather indistinct median band, narrower in the middle. The bands are more distinct beneath. 40—45 mm. Chiriqui. — **crassiorata** *form. nov.* (175 g) is much more intensely and contrarily marked. The ground-colour with its *crassiorata*. reticular lines is not different, but the bands are broad, dark red-brown. The whole costal margin of the forewing is red-brown as far as vein 7, and so is the inner margin as far as the median band. The interior band is distinct, narrow, the median band strangulated above vein 2, the submarginal band interrupted, its apical part situate a little farther outside. Hindwing likewise with a very distinct median band. Beneath only the forewing is paler, red-brown at the costal margin, the bands less distinct than above. ♀ 40 mm. South Brazil. Type in the Senckenberg Museum, no particular habitat mentioned; another specimen from Brazil in the same Museum.

II. Hindwing with an excision or truncate at the apex above vein 7.

D. peripheta *Cr.* (175 e). Forewing only with a slight excision at the anal angle, the margin undulated *peripheta*. in both wings. Wings red-brown with yellow hyaline spots partly crossed by red-brown reticular lines. A few separated spots at the base of the forewing. A very distinct median and exterior band, and one at the middle of the distal margin. Hindwing with predominating hyaline places. An irregular red-brown median band, more or less interrupted. More extensively red-brown enclosing hyaline spots at the apex and anal angle. With an expanse of 85—90 mm it is the largest Thyridid known. Chiriqui and in the West Indies.

D. accipitrina *Warr.* (175 d) is likewise very large. Both wings with a pointed apex, the distal margin *accipitrina*. undulated. Ground-colour whitish yellow, veins and reticular lines pale brown, the bands dark brown. The base of the forewing is faded brown. A broad oblique band proceeds from the middle of the inner margin, and a coniform spot from the anal angle, both uniting above vein 5, from where they extend as a broad band to $\frac{2}{3}$ costal margin. The whitish transparent ground-colour is therefore reduced to a narrow oblique band between the basal spot and the median band, it extends to below the costal margin. Besides a broader light postmedian band, extending to vein 5, and 3 round hyaline spots between veins 4 and 7. Apex whitish. Hindwing narrowly brown at the base. The double band like that of the forewing. The central area narrower, numerous hyaline spots at the apex. A brown streak from $\frac{3}{4}$ costal margin to a brownish cloud at the middle of the distal margin. 70 mm. Described according to 1 ♂ from Bogota.

The following species exhibit a larger excision at the anal angle of the forewing, and a smaller one above it.

D. mirabilis *Stgr.* (175 d) is the strangest Thyridid. Distal margin undulated only on the hindwing. *mirabilis*. Wings somewhat oblong. Forewing pale red-brown. Costal margin interrupted narrowly light in the distal half. Broad hyaline spots at the inner margin as far as the cell and vein 3, one near the base, one each before and behind the middle. Marginal area pale brown. Hindwing with a hyaline spot behind the cross-vein. A somewhat darker band behind it. The exterior band light, distinct only at the inner margin. Darker red-brown spots at the light costal margin. ♂ 70 mm. Peru.

D. rusina *Drc.* (175 f). Distal margin not undulated in both wings. Dull red-brown with hyaline spots. *rusina*. An interior and median spot in the submedian fold, one above them at the cross-vein, divided by dark lines. A larger group of spots in the marginal area upwards as far as vein 5, small ones also above them. Hindwing with a group of spots at the base at the inner margin and a stripe from the anal angle to the middle of the costal margin. In my only specimen the costal margin of the forewing is not nearly so distorted as it is on DRUCE's figure, and the little tail on the hindwing is quite inconspicuous. 52—56 mm. Guatemala, Panama, Venezuela.

D. angulipennis *Dgn.* Forewing with 2 excisions at the anal angle, then straight as far as beyond vein 3, *angulipennis*. where it is well angled or bent, the apex somewhat prominent. Hindwing straight from the anal angle to the apex, slightly angled at the veins. Ground-colour chocolate brown with a lilac gloss, with fine black irregular lines. Costal margin of forewing fine white. In spite of this short description, the species will be recognized by the straight distal margin of the hindwing. ♀ 38 mm. Colombia.

D. stenoptila *Warr.* (175 h). Distal margin undulated in both wings. The shape of the wings is oblong. *stenoptila*. Forewing brownish ochreous, the marking dark brown. Irregularly dull brown at the costal margin. Inner margin dark brown in the middle, from where two dark oblique bands proceed; one of them in the middle to a quadrangular subcostal spot behind the cell; the other one forked, from the anal angle and before it, united above the middle and extending to a broad triangular subcostal spot near the apex. The rest of the wing with numerous brown reticular lines. Hindwing with a spot at the base and a broad interior band, the rest with brown reticular lines. ♀ 32 mm. Trinidad, Honduras. *stenoptila* resembles a small light *denticulata*.

III. Both wings cut out below the apex and thereby angled at the middle of the distal margin. The hindwing of *annuligera* with another angle at the margin at vein 8.

annuligera.

D. annuligera Wkr. Wings greyish red with darker transverse lines. Forewing with black, light-edged circles arranged band-like below the cell and at the margin. On the hindwing these circles are distributed at the inner margin and distal margin, the latter ones partly connected in pairs. 45 mm. Brazil. — *Siculodes mediula* Gn. is presumably the same species.

oleigutta.

D. oleigutta Fldr. (175 f). Distinguished in the contours of the wing from *annuligera* by the undulated distal margin on the hindwing between the angle and the anal angle. Forewing with a slight excision at the anal angle. Forewing hyaline white. The basal area red-brown, somewhat extra-angular at the median vein. Exterior band broad, extending to the base of veins 3—5, then interrupted and narrowly continued from vein 2. The apical area is broadly red-brown, extending down to vein 4, the costal margin behind the exterior band red-brown as far as vein 7, a spot at the anal angle also red-brown. Hindwing red-brown. A large round hyaline spot at the base, a similar one at the costal margin near the apex. Both wings with parallel linear streaks in the hyaline spots. 45—50 mm. Brazil, Surinam.

vitrea.

D. vitrea sp. n. (175 g). A larger excision at the anal angle in both wings than in *oleigutta*, the hindwing not undulated at the margin, the angle smaller than in *oleigutta*. The thorax and the costal margin of the forewing dark red-brown, narrower towards the apex. Red-brown also at the base. Close behind it the interior band, broad in front, bent inwards, ending narrower. A square spot behind the centre of the wing between vein 2 and the inner margin. A discal streak from the anal angle to vein 4, somewhat inwards, blurred on both sides at vein 2. A thick line from the costal margin near the apex to the margin at vein 5. Besides numerous fine reticular lines. Hindwing only with red-brown reticular lines which are close together at the inner margin, more widely meshed elsewhere. ♀ 40 mm. Itatiaya. Type in the Senckenberg Museum in Frankfurt on the Maine.

basiplela.

D. basiplela Warr. The marking and the reticular lines are red-brown. The base of the forewing as far as $\frac{2}{5}$ inner margin and the stripe at the costal margin red-brown. Two dark brown quadrangles below the stripe at $\frac{2}{5}$ and $\frac{1}{6}$ costal margin. A line extends from the interior angle of the first quadrangle to an urn-shaped spot at $\frac{2}{3}$ inner margin. Another line from the interior angle of the second spot to a triangular spot at the anal angle, a thick line from the exterior angle to the middle of the distal margin. The base of the hindwing is narrowly red-brown, a quadrangular spot at the cross-vein and one at the end of the inner margin are also red-brown. Both wings with many reticular lines. 40 mm. Described according to 1 ♀ from British Guiana. *vitrea* may be similar, since it also has a red-brown vein 2 on the forewing.

dismutata.

D. dismutata Warr. (175 g). Similar to *basiplela*. All the brown marking paler, more rusty brown. The basal spot on the forewing covers one third of the length of the wing, the costal-marginal stripe is broader. The second spot below the costal margin is nearer to the apex and not connected with the distal margin. Vein 2 is not red-brown. Hindwing not with a line from $\frac{2}{3}$ costal margin to the distal margin, but only with a short oblique streak near the apex. The pale ground-colour is slightly reddened. Hindwing with red reticular lines. 40—50 mm. Upper Amazon R.

lineigera.

D. lineigera sp. n. (175 h). Wings shaped as in *vitrea*, but the margin of the hindwing is straight below vein 4. Body and wings brownish ochreous. The costal margin of the forewing narrowly lighter, with small dark brown spots from which irregular lines proceed. The interior and median lines straight, somewhat nearer together at the inner margin. The exterior line somewhat undulate, ending at the anal angle, the submarginal line almost vertical from the distal margin at vein 3. Besides a few less distinct lines. Hindwing with a straight median line, an undulated exterior line from the anal angle to $\frac{2}{3}$ costal margin, a submarginal line parallel to it, from vein 3 at the margin. The lines on the forewing beneath are more distinct, on the hindwing only the median line is distinct, the others reticular. ♀ 33 mm. Molinar, Paraguay, FR. SCHADE leg. Type in the Senckenberg Museum.

albiapicata.

D. albiapicata Warr. (175 b). Both wings undulated at the distal margin below the excision. Forewing rusty brown, the lines and spots darker. The costal margin of the forewing dark brown, somewhat lighter at the apex. Brown streaks in the base of the cell with a rusty brown spot at $\frac{1}{3}$ costal margin. An oblique rusty brown line close behind the middle, forked at the costal and inner margins, the lower fork filled with rusty brown. A line extends from the upper fork to a large oval spot between veins 2 and 3, below it a projectile-shaped spot at the anal angle, and a round one above it. Distal margin darker rusty brown, white at the apex. Hindwing with a bent rusty brown line at $\frac{1}{3}$. A small white spot at the lower cell-angle. Spots below the costal margin are confluent outside, a round spot between veins 2 and 3. Apex white. Similar to *frondicula* Gn. (174 g), but with differently shaped wings. ♂ 60 mm. Peru. — We figure a specimen from Ecuador (in the Senckenberg Museum), which slightly differs from the type. The forewing lacks the triangular spot at $\frac{1}{3}$ costal margin. The lower fork of the median line is shaped like a vase below vein 2. The two spots at the anal angle are more fused, another smaller spot is above vein 3, and a few dots are above it. Forewing with veins 8 + 9 stalked, but this may be only abnormal. 56 mm.

timida.

D. timida Warr. (175 g) is the smallest species. Whitish. The veins and fine reticular lines are brown. The costal margin and the basal third tinged with brown. An exterior and submarginal narrow brown band

extend inwards, both thickened at the inner margin. Narrowly brownish at the distal margin. Hindwing with all the transverse bands and lines somewhat connected longitudinally. 1 ♀ 22 mm. Upper Amazon R.

D. fenestralis C. d. Lima has unfortunately remained unknown to us, since there was no access to the original description.

23. Genus: **Meskea** Grt.

Similar to *Zeuzerodes* Pagst. in the shape of the wings, but veins 8 + 9 of the forewing are stalked. There is also a specimen at hand, in which veins 9 + 10 are stalked. For a long time the type *dyspteraria* Grt. was the only species of the genus. Two more species have become known only very much later.

M. dyspteraria Grt. (175 h) resembles *Z. leuconotula* Pagst. (p. 1203) so much that PAGENSTECHER has *dyspteraria*, partly confounded them. Ground-colour of forewing greyish brown, the median vein more intensely white than in *leuconotula*, but the same white apical spot with a black dot. Hindwing more blackish than in *leuconotula*. The broad white submarginal band reaches the costal margin and extends somewhat basad in the submedian fold, it may contain fine black dots. 28—34 mm. Florida, Texas.

M. horror Dyar. Forewing reddish yellow, blackish in the cell, greyer at the margin, with black dots *horror*, which are only absent at the costal margin and more densely arranged in the marginal area. Thus it only differs from *dyspteraria* in the absence of the apical spot. Hindwing also similar to that of *dyspteraria*, but the margin grey with dark dots. In *dyspteraria* it is brown, and the black dots are on the white band. 30—43 mm. Mexico.

M. subapicula Dyar. Greyish yellow. Forewing dusted grey, forming indistinct curved bands in the *subapicula*, distal part. A black longitudinal streak below the exterior part of the cell. Hindwing with a long apex, striated and dusted grey, forming broad bands through the centre and at the distal margin. 19—21 mm. Mexico. The larva does much harm to cotton.

24. Genus: **Endolophia** Hmps.

Palpi long, erect. Abdomen long. All the veins of the forewing free, vein 8 absent. Veins 6 and 7 of the hindwing separated, long hairs beneath at the inner margin. Only 1 species.

O. hypohaemia Hmps. Body and wings glaringly red-brown, somewhat grey and brownish ochreous in *hypohaemia*, some places, striated darker red. Forewing with a dark spot at the cross-vein. Both wings with a bent greyish-ochreous exterior band and a narrow submarginal band. Under surface intensely reddened. ♂ 16 mm. Surinam.

25. Genus: **Hepialopsis** Warr.

Forewing very long, straight at the costal margin, slightly excurved at the inner margin at the base. No veins stalked. Hindwing smaller, oblong, its inner margin very short. Veins 6 and 7 from the same base. Abdomen of ♀ long, legs short and strong. Only 1 species, characterized by its name.

H. sphingipennis Warr. (175 h). Forewing yellowish grey, dusted darker. These scales form rows of *sphingipennis*, indistinct spots, which are larger and more distinct in and below the cell. Less dusted and more yellow at the distal margin. Hindwing dark grey with a reddish reflection. A thick red-brown submarginal line proceeds from the anal angle, with 2 parallel lines or a broad band above it. The hindwing is said to be somewhat similar to that of *Sphinx ligustri*. 60 mm. 1 ♀ from Peru.

26. Genus: **Orneostoma** Warr.

Forewing with an undulated costal margin, projecting in the middle, cut off before the apex. Distal margin bent, incised above the lobate anal angle. Inner margin lobate at the base, then bent inwards. Veins 9 + 10 stalked, 5 and 6 from the angles of the cross-vein. Hindwing bent forward at the base at the costal margin, the distal margin straight. Type: *subpulchra* Warr.

D. subpulchra Warr. (175 h). The forewing with a pale brown subcostal stripe, quite straight from the base to *subpulchra*, the apex. Whitish below this stripe with dark reticular lines. A dark band at $\frac{1}{4}$ of the length of the wing, slightly strangulated in the middle. A dark grey triangular postcellular cloud, connected at the apex with a quadrangular spot at the middle of the inner margin. The marginal area is broadly dark greyish brown, bordered by a white area inside, which bends narrowly round to the apex and is broad at the inner margin. Hindwing entirely dark brown, indistinctly darker between the veins. The description is not quite correct. 1 ♀ 35 mm. From Peru.

D. albitessellata Hmps. is somewhat more marked. Body and wings grey with dark brown little streaks, *albitessellata*. Forewing with a reddish brown stripe with dark brown streaks below the base of the cell and in the upper cell-end. An oblique triangular white spot with red-brown streaks from the base of vein 2 to the inner margin. A small spot at the middle of the inner margin, an exterior spot from vein 4 to the inner margin and a white

streak at the middle of the costal margin with red-brown little streaks. A spotted band from the costal margin near the apex to the distal margin at vein 4. The interior line of the hindwing is replaced by a white spot in and below the cell, with small black streaks. A black spot with a reddish yellow centre is below the middle of the cell, and a small similar one at the lower cell-angle. Another one at $\frac{2}{3}$ costal margin and an elliptical one between veins 4 and 1. Striated red-brown at the apex. 30 mm. Also described according to a single ♀ from Peru.

Alphabetical List

of the original descriptions of the forms of the American *Thyrididae*.

* signifies that the form is also figured at the place quoted.

Family: Aegeriidae.

The *Aegeriidae* are a well defined family apparently allied to the *Cossidae*, since they have the same larval habits. But this is also the only link connecting them with the wood-borers, for the wings and neurulation of the *Aegeriidae* are quite differently shaped from those of the *Cossidae*. At any rate it is certain that the family has originated from an old tribe, which is proved by its slight variation and, above all, by its rather equable distribution over the various zones. They are generally assumed to have developed from the *Tineidae*; but this development must be supposed to have been far extending, as the *Tineidae* are primitive, nocturnal insects, whereas the *Aegeriidae* are throughout insects loving the sun and flowers and very much inclined to mimicry. FORBES presumes them to be closely allied to the *Yponomeutidae*, while in PACKARD's opinion they originate directly from the *Thyrididae*. That is why they are also ranged among the Microlepidoptera in all the latest treatises, but future research must decide whether this is quite correct.

The general habitus is almost invariably the same. Small to medium-sized species, the greater part at any rate rather small, most of them being rarely encountered; some of the species, however, may occasionally do much harm. Their rareness is not only due to the difficulty of discovering them, but also to their enormous resemblance to Hymenoptera, by which they are most excellently protected against persecution. The German name of "Glasflügler" (clearwings) distinctly shows that most of the species have narrow, elegant and hyaline wings. Some, of course, have the forewings entirely or partly scaled, but few also the hindwings; but even in these cases there are some hyaline places to be noticed. In addition to this resemblance to wasps or bees, the black ground of the abdomen is also frequently striped yellow or orange, in any case vividly striped; in some species there is even yet a sham sting, as in the *Alcathoe*-species. Owing to their frequently long legs and their strikingly hymenopterous flight they are only to be discovered by expert collectors from among the crowds of insects visiting blossoms. Only the persevering collector who has much practice in discovering and capturing these insects which are often very shy besides, becomes aware that the majority of the *Aegeriidae* are not at all so very rare, especially if one examines their regular feeding-places, and a more thorough experience will also be rewarded with better success. Species which, as a rule, are but rarely found and in single specimens, can mostly be obtained in greater numbers by breeding, as soon as the food-plant of the larva has been found. It is generally easy to obtain pupae from the adult or almost adult larvae; according to the circumstances of the habitats, the insects which always live an endophagous life must be accommodated if possible according to their natural conditions, those occurring in branches and trunks of higher trees for instance *Sphecia*, *Aegeria*, *Paranthrene*, many *Synanthedon* etc. must be kept dry, others again such as *Dipsosphecia*, *Chamaesphecia*, *Bembecia*, certain *Melittia* living in roots or the parts of plants growing above them, must accordingly be kept damp, if possible together with the whole root-stock; many prefer carcinoid places or galls produced by Hymenoptera.

The larvae, like all the insect larvae living in retreats or in the dark, are bone-coloured or whitish, only the intensely chitinized mandibles and the head are darker, — from brown to black; the dorsal receptacle often shines through the thin, not very bristly or sometimes quite smooth skin, the three pairs of pectoral legs are well developed, but above all the false feet and anal legs by which they can immediately be distinguished from the larvae of capricorn beetles frequently living at the same time in similar places. Most of the species have a larval stage of one year only, some of them of two or even three years. When they are small they penetrate into injured parts of the attacked plant and, in their first stage, bore irregular passages below the bark, proceeding as far as the inner bark. After hibernating many living in colder regions go deeper into the wood. Some few prefer dry, withered wood, most of them however like fresh wood. The passage of the adult larva is invariably circular, whilst the capricorn beetles according to their shape leave almost oval passages and loopholes. When the time of pupation sets in, all the Aegeriid larvae remaining in the passages bore themselves as far as the

outermost part of the bark, only leaving a cuticle as thin as paper, which can be easily pierced by the advancing pupa. Some pupate out in the passage, others shut off the passage above besides with a small finely spun lid, very many make from the nibbled fragments of woody fibres and faecal remnants a cocoon which is as soft as silk inside and which is slightly closed near the head or can be lifted like a lid, so that the emerging insect devoid of any biting jaws may be able to get out; others leave even the trunk and spin themselves a cocoon in the soil. On its abdominal segments the pupa has coronae of short hard chitinous bristles enabling it to climb within its burrow and to bore itself out while emerging; the empty chrysalis shell then protrudes from the burrow long after the pupa has emerged. In spite of their concealed habits many species are much infested by parasites, so that it frequently occurs that instead of the expected lepidoptera a large number of parasitic Hymenoptera appear. The development of the emerged lepidoptera mostly (in the smaller species invariably) proceeds very quickly, sometimes in a few minutes, and as soon as the insect is able to fly, the desire for copulation springs up. Most of the *Aegeriidae* are fond of visiting flowers. In dull weather the lepidoptera are often found, like the *Zygaenidae*, resting on blossoms or on stalks and trunks, where they are easily captured by collectors.

If the outlet-tube is made, one can easily crush in or blow off the thin cuticle by brushing the trunks with a wire brush and thus lay open the passage by chiselling it out or sawing it off. First condition, however, is that the pupa remains enclosed in the passage; every pupa that is taken out will perish without exception. Low plants, when attacked, almost invariably show a sickly exterior, yellow leaves, less developed blossoms etc., so that it is likewise easy here to get hold of the larva or pupa by pulling these plants out or by breaking them off. — When catching them with the net, one must go to work very quickly and carefully, as the nimble little insects whirl about, and both the scales and fringes being but loosely fitted, it is very difficult to obtain quite undamaged specimens in this way. The legs are likewise very loosely attached and easily break off, which is all the more regrettable since the determination of a species is frequently rendered difficult by their absence, because the species are more easily distinguished by the spines, the hair and often also the colouring of the legs. Especially striking is the fur-like hair, which resembles the coating on a bee's legs, on the tibiae and tarsi of the *Melittia*-species which are especially common in tropical and subtropical regions and of which considerable number of species are already known. The *Aegeriidae* copy bees so well that a *Melittia* sucking blossoms not only exhibits mostly bright-coloured hair on the hindlegs but also the habit of the copied bee of keeping still with its wings folded up, when creeping into the blossom, and then stretching its legs hindways with the fictitious velvet trousers.

Contrary to other faunistic regions, America harbours an enormous number of *Synanthedon* species, as nearly half of all the species known from there belong to this genus. Although we must admit that some of them are not properly grouped at present, as for instance *S. animosa*, *behrensi*, *geliformis*, *fragariae*, *sapygaeformis*, *polygoni*, *achillae* etc., yet a considerably larger number of *Synanthedon* remains for America than for the rest of the world. As the *Synanthedon* species in other regions, and as far as is known in America too, are without exception tree and shrub inhabitants, the vast forests of the north, as well as the primeval ones of the south have favoured the development of this genus. The species mentioned, and a few more besides, will have to be classed among *Chamaesphecia* and *Dipsosphecia* for which also their "swarming over the steppes of the earth" speaks. Besides these two genera are unnaturally sparsely represented otherwise in the American Fauna.

Without doubt, only a part of all the existing species is known, even in North America which is comparatively well combed through, here and there new species constantly come to light, while Central and South America supply a great many more. The estimate that to the 300 or so known species there will come in the course of time a half or at least a quarter as many again, before an approximate close of new discoveries can be spoken of, is very probably correct. On the other hand, it must be said that many a single specimen described as a species will turn out to be a missing sex of another or a synonym.

The preparation and keeping of the *Aegeriidae* is particularly difficult because the insects, above all the ♂♂, very soon get oily and besides also cause verdigris to form on the needles, so that it is best to use black or still better Krupp steel needles from the first. Specimens which have flown are less subject to this appearance, which is attributed by many to diminished moisture and the using up of certain juices and the corrosive fatty acids contained therein. The well-known method of breaking off the abdomen is hardly possible on account of the many loose scales and the possible damage when sticking them on again. It is therefore better to put the specimens so attacked right into deoiling liquid, as the whole body is generally affected. Light-petrol cleans fairly well, but better is sulphuric ether and carbonic disulphide; the vessels must be tightly closed as the substances mentioned evaporate quickly and are inflammable. 24 hours are usually sufficient, stubborn cases need a second treatment. After having been used several times the liquid must be renewed, as too much of the extracted fat will have collected, shown by the slightly yellow tint. Very finely powdered bole deoils quite well otherwise, but cannot be used for *Aegeriidae*, as the extremely sensitive, fragile legs and antennae do not permit

dusting. After taking them out of the bath and the drying which lasts only for a short time, the hair on the thorax and abdomen as well as the fringes of the wings can be smoothened with a small soft hair-pencil.

In the classification we have followed JUNK's Catalogue Pars 31, as was done in the African and Indo-Australian Faunae, too; the grouping is very natural and affords an easy perspicuity. Concerning the figures we have often preferred copies of good figures from BEUTENMÜLLER's "Monograph of the Sesiidae of America" and OBERTHÜR's "Études de Lepidopterologie comparée" to figures from nature according to damaged or badly discernible specimens in collections, especially since the mostly delicate insects, as we mentioned above, easily become oily and inconspicuous.

1. Genus: **Lepidopoda** Hmps.

Palpi erect, reaching the frons. Proboscis present. Antennae of ♂ ciliated, plain in the ♀. Middle tibiae hairy, hind tibiae and the two first tarsal joints densely haired. All the veins present in the forewing, 7 + 8 stalked. Hindwing: 3 + 4 stalked, 5 absent, 6 arising close at 7. Type: *L. heterogyna* Hmps. from India.

L. infera Meyr. Head, palpi, antennae, thorax, and abdomen violettish black; hind tibiae with violettish black hair, an orange hair-tuft at the apex. Wings hyaline, with black veins and margins, the anterior half of the forewing mixed with yellow, the costal part blackish, except a short yellow streak between 9 + 10 at the base, the cross-vein black. Hindwing transparent, with black veins and margins. Only 1 ♂ known. 16 mm. Para. Brazil; taken in July.

L. homotropa Meyr. (176 a). Head, thorax and abdomen dark bluish green; face and palpi white; antennae dark brown; hind tibiae with dark purple hair, a whitish central spot, the anal hair mixed with orange; wings hyaline, with black veins and margins and dark grey fringes, the forewing in front mixed with yellowish, the costal area as far as the cell and vein 9 dark brownish, a very fine whitish ochreous line at vein 11, the cross-vein finely edged with reddish, hindwing hyaline, margined with black. Described according to 1 ♂. 14 mm. Brazil, Manaos, November. We figure the species according to a specimen collected by Dr. SEITZ in South Brazil.

2. Genus: **Pseudoalcathoe** Le Cerf.

Palpi normal, proboscis present, antennae finely dentate. Legs long and thin, abdomen long and delicate, ending in the ♂ into a very long and thin tail-like continuation which is scaled as in *Alcathoe* Harr. and *Cryptomima* Hmps. Vein 1 of the forewing short, not parted at the base, 2 + 3 from the interior angle of the cell, 7 + 8 on a very long stalk, 10 from the upper angle of the cell, 11 very thick, its last third united with 10. Hindwing: 1 a present, 2 from the interior angle of the cell, 3 + 4 from the cell itself, on a short stalk, 5 from the angle, 7 absent. Type: *Ps. chatanayi* Le Cerf.

Ps. chatanayi Le Cerf (176 a). Head and face greenish black, palpi black, the third joint white beneath. Antennae yellowish orange, at the base black above, brown below. Collar and thorax blackish green with a bronze reflection; abdomen blackish green, the last joint with a bluish reflection outside, the tail-shaped appendage blackish green, of about $\frac{3}{4}$ of the length of the abdomen. Forewing blackish green excepting the distal parts which are black warming into brown. Hindwing purple black, the base and costa blackish green, the fringes of all the wings blackish brown. Legs blackish green. 33,5 mm. Only 1 ♂. From the Volcano of Chiriqui in Costa Rica, May. An entirely isolated Aegeriid resembling wasps from the genus *Sirex* or also *Ephemeridae*.

3. Genus: **Parasesia** Le Cerf.

Medium-sized. The first palpal joint rather long, the second bent, the third oblique and longer than half of the second. Antennae relatively short and thick. Tongue well developed, eyes small. Body long, anal tuft like that of a *Tinthia*, slanting when seen from above downward. Wings transparent, vein 2 of forewing arising from 3 far before the interior angle of the cell, 7 + 8 are stalked, 10 is absent; vein 1 of the hindwing is obsolete, 2 + 3 arise from the same place, the posterior angle of the cell, 7 absent; besides there is a small, but well visible anal lobe. Type: *P. cristallina* Le Cerf.

P. cristallina Le Cerf (176 a). Face blackish brown, white before the eyes. Palpi and antennae black. Collar, thorax, abdomen and anal tuft black, the 4th segment with a line of whitish yellow scales, the 4th, 5th and 6th segments edged with whitish yellow. Anterior hips brownish black, mixed with yellow scales outside and above, femora brownish yellow, yellow inside, tibiae and tarsi yellow. (Middle and hind legs absent.) Forewing transparent, the veins, a fine marginal line and the discal vein dull brown, some scales between veins 8 + 9 dingy yellowish red, the interior margin and the outside of the discal vein the same, the base of the wing black; hindwing transparent, the veins and marginal line dull brown, the interior margin reddish yellow from the middle of the anal lobe to vein 1. Beneath all the wings are dusted with a more glaring yellowish red, the

fringes greyish bronze. 24 mm. Brazil, Prov. of Rio de Janeiro. August till September. Only 1 ♀ known hitherto. — The type is without the middle and posterior legs. nevertheless LE CERF considers it necessary to establish a new genus for this species.

4. Genus: **Synanthedon** Hbn.

Tongue well developed. antennae thickened shortly before the end with a small hair-bristle at the end, mostly feebly ciliated in the ♂. The forewing always with all the three hyaline areas, veins 10 + 11 extending parallel with the distal margin. Hindwing with veins 3 + 4 on the same short stalk. — Type: *S. respiiformis* L. from Europe.

- giliae*. **S. giliae** Hy. Edw. (= *vitrina* Neum., *deceptiva* Beut.) (177 a). ♂: head black, face pale yellow, palpi yellow, with black hair outside, collar yellow in front. Antennae black, thorax black with a few yellow hairs at the end of the patagia. Abdomen black with yellow bands on the 2nd, 4th and the last two segments, the under surface also with bands or sometimes quite yellow. Anal tuft yellow, black above. Legs yellow with black bands on the tibiae. Forewing transparent with narrow black margins and a strong cross-vein, the latter outwards frequently with red. Hindwing transparent with narrow black margins. — ♀: head black, face and palpi yellow. Wings with brown margins, the discal mark brownish orange outwards, quite orange below. Abdomen with three yellow bands on the 2nd, 4th and 6th segments. Under surface with traces of a band on the 5th segment. Anal tuft yellow mixed with black. 20—25 mm. Colorado, Montana, British Columbia, Huachuca Mts., Arizona.
- rileyana*. **S. rileyana** Hy. Edw. (176 a). ♂: head black, face and palpi yellow, black outside. Collar yellow in front and behind. Thorax black, patagia yellow behind, a yellow transverse streak and yellow spots at the base of the forewing. Antennae black, distinctly pectinated. Abdomen black with six lemon-coloured bands, the basal segment without a band or with traces of it. Anal tuft black and yellow. Legs yellow with black bands. Forewing transparent with narrow black margins, the discal mark broadly red, beneath as above, but the costa yellowish. Hindwing transparent with narrow brown margins, the cross-vein finely red. ♀: similar to the ♂, but with only five yellow bands, the anal tuft black. Forewing with a broad brownish bronze costal margin, a very broad distal margin, so that the transparent spot in the distal area becomes very small. Cross-vein strong, brown, red outside. Beneath the costal and inner margins yellowish. The distal areas between the veins red. Hindwing with broader margins than in the ♂, beneath more or less reddish. 20—30 mm. —
- hyperici*, *brunneipennis*. var. **hyperici** Hy. Edw. shows a very thin costal -marginal streak of the forewing. — In var. **brunneipennis** Hy. Edw. (176 a) the margins of the forewing are so broad in the ♀ that very little remains transparent.
- mimuli*. **S. mimuli** Hy. Edw. Head black, face white, palpi dingy white, outside mixed with brownish hairs. Antennae black, thorax black, all the yellow markings of *rileyana* being dingy whitish yellow here. *S. mimuli* may be a local variation of *S. rileyana* (176 a). Only 1 ♂ known. 21 mm. Colorado.
- bibionipennis*. **S. bibionipennis** Bsd. (= *chrysidipennis* Bsd. ♀, *aureola* Hy. Edw., *hemizonae* Hy. Edw., *lupini* Hy. Edw., *perplexa* Hy. Edw., *impropria* Hy. Edw., *rutilans* Hy. Edw., *washingtonia* Smith, *madariae* Smith) (176 b). ♂: head black, palpi yellow, with black stripes outside, the collar and the underside of the thorax yellow. Antennae and thorax black, patagia feebly yellow. Femora black, tibiae black outside, yellow inside, tarsi yellow. Abdomen black with rather broad yellow bands on the 2nd and 4th segments, sometimes with a yellow dot on each side. Anal tuft black, yellow beneath. Forewing with broad brownish black margins, yellow in the distal margin between the veins, the rest transparent. Discal mark broad, black. Under surface golden yellow. Hindwing transparent with brownish black margins and a yellow base along the inner margin. — ♀: head black, palpi and collar with yellow bands on the 2nd, 4th, 5th and 6th segments. The band on the 5th segment may occasionally disappear. Anal tuft yellow, black in the middle above. Legs more yellow than in the ♂. Forewing blackish brown, broadly bordered with orange, so that still less is transparent than in the ♂. Under surface deep golden yellow. Hindwing transparent, distal margin blackish brown, before it a more or less prominent dark yellow line. 13 to 22 mm. June, July. Nova Scotia, Northern New York, Minnesota, Utah, Nevada, Colorado, Idaho, Texas, California, Oregon, Washington, Vancouver, British Columbia. — The larva is common and does much harm, especially in the Pacific States, to the roots of the pine-strawberry, also to blackberries and raspberries.
- arctica*. **S. arctica** Beut. (177 b). Head, palpi and thorax quite black. Abdomen black with a narrow white band on the posterior edge of the 2nd and 4th segments, anal tuft black. Legs black, hind tarsi dingy white. Forewing transparent with black margins and a broad black cross-vein. Hindwing the same with narrow black margins. Forewing beneath dusted with golden yellow basally. 20 mm. Only 1 ♂ known. Kodiak, Alaska, July.
- neglecta*. **S. neglecta** Hy. Edw. (176 a). Head black, dingy yellow in front, palpi yellow, antennae black. Thorax black with narrow yellow lateral and dorsal stripes. Abdomen black, the 2nd and 4th segments edged with

pale yellow behind. Anal tuft black. Legs yellow and black. Forewing purple brown, the hyaline area and distal area strewn with transparent golden yellow, the under surface more or less golden yellow. Hindwing transparent, distal margin purple, dusted more or less golden yellow, especially at the base; fringe dark. 15 to 17 mm. California, Washington. Only the ♀ is known.

S. refulgens Hy. Edw. (177 a). ♀: head and antennae black, palpi and collar yellow. Thorax black *refulgens*, with a yellow transverse band on the posterior part, and with yellow hairs at the posterior end of the patagia. Abdomen black with yellow bands on the 2nd, 4th and 6th segments and traces on the 5th segment. Anal tuft black with upper yellow sides. Legs yellow and black, femora black, tibiae yellow with black bands, tarsi yellow. Forewing violettish brown with orange scales on the otherwise transparent parts, the cross-vein orange outside. Hindwing transparent with violettish brown margins. 18 mm. The ♂ and the early stages are unknown. Georgia.

S. bassiformis Wkr. (= *lustrans* Grt., *eupatorii* Hy. Edw., *infirmata* Hy. Edw., *imitata* Smith) (176 b ♂, *bassiformis*. 177 b ♀). Head metallic blackish bronze, the orbita white, collar and palpi yellow. Antennae black with a blue reflection. Thorax metallic blackish bronze with a feeble yellow line on each side and a posterior yellow edge. Thorax below with yellow scales on each side. Abdomen slender, violettish brownish black with narrow yellow rings on the 1st to 4th and 6th to 7th segments. Anal tuft like a broad fan, brownish black, yellow beneath on each side. Abdomen beneath yellow along the middle. Legs yellow, more brown inside. Forewing transparent with narrow bronze brown margins, distal margin rather broad with yellow scales between the veins, the cross-vein strong. Beneath yellowish. Hindwing transparent with narrow brown margins. The ♀ is stronger and has only 5 yellow margins on the abdomen. Anal tuft yellow with few brownish black hairs. Antennae with a long white preapical spot. 18—26 mm. New York, Massachusetts to the south as far as Texas and to the west as far as Nebraska and Colorado. — var. **sexfasciata** Hy. Edw. (= *bollii* Hy. Edw.) has only four *sexfasciata*. hyaline cells, and broader distal margins. — var. **consimilis** Hy. Edw. has the 5th and 6th segments without *consimilis*. any yellow. The larva lives in the stalks of *Eupatorium purpureum*).

S. corni Hy. Edw. Head black, palpi orange, the orbita white. Collar dull orange, antennae black, *corni*. yellowish white before the tips in the ♀. Thorax deep black with narrow yellow stripes on each side, with a posteriorly yellow transverse streak. Abdomen slender, deep purple or bluish black with very narrow rings on the 2nd and the last 3 segments, pale yellow beneath. Anal tuft black above, bright reddish orange below, quite red in the ♀. Legs bluish black, tibiae and tarsi with yellow rings, anterior coxae yellow. Forewing transparent with a narrow bluish black inner margin, a broader costal and distal margin and a strong cross-vein of the same colour. Hindwing transparent with narrow black margins. 18—21 mm. Massachusetts, New York, Pennsylvania, Ohio. The larva does not live in *Cornus*, as might be assumed, but in *Doellongeria umbellata* (a white aster), in damp, swampy places in the stalk and the lower parts; in May it eats a few inches upwards and constructs a pupal window which can be easily pierced by the imago after the three weeks' pupal stage. From the middle of May to the middle of July, the ♂♂ fly to the blossoms in the sun in the morning, while the lazy ♀♀ can be easily taken away with the killing-bottle, as they remain sitting on the food-plant or close by. In looking for them, the stalks occupied by them easily break off; larvae not yet having pupated in May are sure to be infested by parasites.

S. asema sp. n. (176 b). Antennae black, broadly white preapically. Head and thorax black, the thorax *asema*. with yellow lateral lines. Abdomen black, the 1st segment yellow in the middle, the following ones finely edged with light yellow behind. Anal tuft orange. Forewing hyaline, the margins, veins and the relatively broad distal margin black; hindwing hyaline, the veins black; the margins of all the wings blackish grey. Legs black, yellowish at the joints. 15 mm. Itatiaya Mts. in the State of Rio de Janeiro. ♂ type in the Coll. MARTEN (Königstein i. T.).

S. wagneri Le Cerf (176 b). Forewing hyaline, the transparent areas developed as usual, the veins and *wagneri*. fringes black, the distal area traversed by 5 veins, a few yellow scales at the discocellular vein, beneath the inner margin and the margin before the distal area yellowish. Hindwing hyaline, with black veins and fringes. Head black, face bronze-coloured and yellowish white. Antennae long and fine, black, shortly ciliated. Thorax greenish black, edged on each side with a somewhat oblique yellow line. Palpi black, the first joint and half of the second mixed with white. Abdomen black, sprinkled with yellowish beneath, the first segment with traces of a yellow median line, on each side a yellow lateral line which is strongest at the base. Anal tuft long, black with a few white hairs. Legs blackish blue, the femora of the middle and hind legs yellow inside, the tibiae yellow in the middle and outside at the end. 18.5 mm. Mistol Paso, environs of Icaño, Argentina. November, December.

S. surinamensis Mschlr. (176 b). Size of *tipuliformis*, but with narrower wings and a much longer and *surinamen-* more slender abdomen. Antennae long, black above below, white towards the apex. Palpi blackish brown *sis*. above and outside, light yellow inside and at the tips. Eyes snow-white in front. Head blackish brown, face metallic green, collar finely edged with yellow. Thorax blackish brown, patagia broadly edged with brimstone colour in front, then more narrowly so, the posterior edge of the thorax likewise brimstone-coloured. The sides of the breast broadly brimstone-coloured. Abdomen blackish brown, the ♂ with yellow longitudinal spots on the middle segments, the ♀ with all the segments finely edged with yellow. The underside in the ♂ with a whitish

yellow longitudinal stripe, the ♀ beneath blackish brown, only the first and the three penultimate segments dusted band-like with whitish yellow, small golden yellow spots on the sides. The broad anal tuft black, whitish yellow on the sides in the ♂, in the ♀ at the end all round golden yellow, hairy, whitish before it. Abdomen of ♂ longer than that of the ♀. Legs blackish blue mixed with whitish yellow. Forewing transparent, the costal margin, distal margin and transverse band narrow, black. The marginal area with 5 veins in the ♂, the two last forked, with only 4 veins in the ♀. Hindwing, margin and veins finely black, costal margin delicately golden yellow. 18—19 mm. Paramaribo and in Rio de Janeiro; figured according to a specimen collected by Dr. SEITZ in the Itatiaya Mts. in February.

whitelyi.

S. whitelyi *Drc.* Head, antennae and tegulae black, thorax brown. Abdomen black, each segment with yellowish brown rings, a broad yellowish brown spot on the 2nd segment. Anal tuft brown and black. Legs yellowish brown. Forewing hyaline, costal margin, veins and apex black, a black streak at the end of the cell, the inner margin strewn with yellow. Hindwing hyaline, veins and distal margin black. 25 mm. British Guiana.

laticraspedontis.

S. laticraspedontis *sp. n.* (176 b) is allied to *wagneri* *Le Cerf* (176 b), but it has quite yellow palpi. Thorax black, posterior margin yellow. Abdomen black, slightly dusted with yellow, the posterior margin of the 4th and 6th segments yellow. Anal tuft dull black, yellow below, the 2nd, 4th, 5th and 6th segments on the ventrum broadly edged with yellow. Legs yellow, femora and the end of the tibiae black. Forewing transparent, the veins, the discal vein and the very broad distal margin black, the inner margin broadly dusted with yellow; beneath the costal and posterior margins as far as the discal vein are broadly yellow, the discal vein and distal area black, the latter powdered with white. Hindwing transparent, the veins and margins black, the last part of the discal vein colourless. The fringes of all the wings yellowish brown. 19.5 mm. Brazil, Itatiaya, January. 1 ♀. Type: Coll. MARTEN.

xanthoneura.

S. xanthoneura *sp. n.* (177 a). Head black, with yellow hair behind. Palpi yellow, the 1st and 2nd joints very hairy, the 3rd short, pointed and blackish. Antennae black. Thorax black with medium strong yellow lateral stripes. Abdomen black with a yellow lateral line. Anal tuft black, yellow below. Forewing hyaline, the transparent areas normally developed; the costal margin, distal margin and discal vein black, the most extensively black in the apical angle. Inner margin, the margin before the distal area and the veins yellow. Hindwing hyaline with normally black margins and yellow veins. Femora of all the legs black, tibiae yellow, the posterior ones with long light terminal and middle spurs, the tarsi with yellow and black rings. 19 mm. 1 ♂. Villarica, Paraguay. — It belongs near to *S. wagneri* *Le Cerf*, from which, however, it is above all easily discernible by the entirely yellow veins, besides the differences mentioned above. Type: Coll. ZUKOWSKY.

guyanensis.

S. guyanensis *Le Cerf* (? = *surinamensis* *Mschlr.*) (176 c). Head blackish blue, the face bronze-coloured, broadly white before the eyes, the 1st joint of the palpi black, the 2nd yellow below, black laterally at the base, above and outside, the 3rd black above, yellow below. Antennae blackish blue. Collar lustrous blackish bronze, thorax blackish blue, laterally edged with yellow, spotted yellow below. Abdomen blackish blue, the 2nd, 4th and 6th segments edged with yellow, the anal tuft black, a few yellow hairs laterally. Ventrums black, the 1st segment partly yellow, the 1st, 2nd and 3rd laterally yellow and the margin of the 4th quite yellow. Legs black and whitish. Forewing transparent, the margins, veins and discal mark chiefly blackish blue, the discal vein is very narrow, the distal margin broad, the exterior hyaline area quadrangular, traversed by 5 veins, the costal vein and distal margin beneath yellowish. Hindwing transparent, the veins, margins as well as the fringes of all the wings purple black. 18—20.5 mm. French Guiana. Only ♀♀ are known so far. — var. **clara** *Le Cerf* (177 a) is distinguished by a much narrower distal margin which appears concave at the apex at the previously forked veins 7 + 8, where it bends round and becomes broader. 19 mm. French Guiana. — Though the species seems to be closely allied to *surinamensis* *Mschlr.*, *Le Cerf* considers *guyanensis* to be a separate species.

anomaliformis.

S. anomaliformis *Wkr.* Blackish purple. Face white, palpi yellow, the 3rd joint only of half the length of the 2nd. Antennae ochreous, plain, thickened before the end. Thorax with three yellow stripes, breast yellow. Abdominal segments with yellow posterior margins, underside and the long anal tuft yellow. Legs yellowish. Forewing transparent, with a purple reflection, the margins and the cross-vein coppery brown, fringe the same. Hindwing transparent, fringe coppery brown. 17—18 mm. Specimens are also reported with more or less black antennae. Tapajoz, Villa nova. Only ♂♂ known.

basalis.

S. basalis *Wkr.* (176 c). ♂: golden yellow. Face silvery white like the orbita. Proboscis very short. The 3rd palpal joint pointed, half as long as the 2nd. Antennae long, black, with an apical hook. Thorax coppery with three yellowish stripes. Abdomen above purple, the posterior margins of all the segments silvery. Anal tuft very long, black, silvery beneath at the base with projecting hair-tufts on the sides. Legs long, hind femora blackish, hind tibiae black at the base. Forewing transparent, the veins, the margin and the transverse line purple, hindwing transparent with purple margins. ♀: palpi longer, antennae shorter, thorax with two broad coppery stripes. Abdomen long fusiform. Legs quite golden yellow. 24—25 mm. Ega. — It resembles *anomaliformis* and *dinetiformis* (p. 1223), but it is especially distinguished by the compressed body.

flavipectus.

S. flavipectus *Le Cerf* (176 c). Head blackish green, bright, face white with a bronze central spot. Palpi yellow mixed with black hairs at the end of the 2nd and 3rd joints. Antennae, collar and thorax blackish blue. Breast below almost entirely yellow, near the hips silvery white. Abdomen blackish blue, the 1st and 2nd seg-

ments yellow on the sides, the 2nd, 3rd and 4th segments with indistinct yellow rings, the anal tuft black, yellow below. Ventrums black, the two first segments whitish, the middle of the five following segments and the outsides of the last golden yellow. Legs black, mixed with yellow. Forewing transparent; margins, veins and discal vein black. Distal margin broad, straight inwardly, so that the exterior hyaline area becomes quadrangular. Dusted yellowish beneath. Hindwing transparent, veins black, discal vein absent. Fringes of all the wings black. 12.5–15 mm. Parana.

S. pittheis Drc. Head, thorax and antennae black, front of the head and thorax beneath yellow. Tegulae black with yellow stripes. Collar yellow. Abdomen brownish black, each segment with yellow stripes, alternately one broader than the other. Anal tuft brownish yellow. Legs yellow. All the wings hyaline, forewing with a brown costal margin and apex, a black streak at the end of the cell, the veins and distal margin brownish yellow. 19 mm. Amazons, Ceará.

S. peruviana Drc. Head, palpi, antennae, collar, tegulae, and thorax black. Abdomen black, the two first segments dark brown. Legs pale yellowish brown. All the wings pale yellowish hyaline, veins dark brown, fringe brown. 25 mm. Peru, Chanchamayo. La Mercede 1000 m. Only 1 ♂.

S. guatemalena Drc. (176 c). Forewing transparent, scantily scaled yellow near the base, costal margin and apex brown. Hindwing hyaline, fringe brown; all the wings strongly iridescent. Head, palpi and antennae below pale yellow, above black. Abdomen black, with yellow bands, below quite yellow. Legs yellow, the ends of the tibiae black. 28 mm. Guatemala, San Geronimo.

S. helena Drc. All the wings clearly hyaline, the costal and distal margins brownish black. Head, thorax and abdomen purple black, anal tuft orange. Antennae black from the base to the middle, then orange, the tips again black. The undersides of the head, thorax and abdomen as well as the legs orange. 32 mm. Mexico, Amula, Guerrero, 2000 m. August.

S. senta Drc. (176 c). Forewing hyaline, costal margin, discal mark and distal margin black; a diffuse black spot near the apical angle in the distal hyaline area. Hindwing hyaline, fringe black, antennae, head, thorax and abdomen black, palpi black above, white below. Collar white. Legs black, hair-tufts on the tibiae of the hindlegs. 15 mm. Guatemala, Panzos.

S. hela Drc. (176 c). Forewing black with a very narrow hyaline spot at the end of the cell. Hindwing hyaline with a broad black distal margin and black fringe. Head and antennae black, the latter with a narrow white ring near the tips. Front of thorax and the tegulae yellowish brown. Thorax, abdomen and legs dull black, thorax beneath yellowish. 16–18 mm. Mexico. Atoyac, Vera Cruz. April; Teapa, Tabasco, January.

S. harti Drc. Head, antennae, collar, thorax and tegulae black, the latter edged with yellow. Palpi black, white below. Abdomen lustrous bluish black, the base, the 2nd and 4th segments with yellow rings. Anal tuft bluish black. Legs black with yellow rings. Both wings transparent. Veins and margins quite black. 20 mm. Trinidad (Port of Spain).

S. sciophilaeformis Wkr. Dark purple. Head golden yellow with white orbita. Palpi black, white below. Antennae black, rust-coloured at the base, somewhat longer than the thorax which is somewhat buff sideways. Posterior margins of the abdominal segments and anal tuft dingy yellow. Tarsi and ends of the tibiae golden yellow. Wings transparent with golden yellow veins. Forewing along the costa and the discal vein purple, distal area golden yellow. 18 mm. Pará. Only 1 ♀ known.

S. deceptura Btlr. Wings hyaline, veins black. The costal margin of the forewing purple black, inner margin, discal streak and the broad distal margin bronze brown. Hindwing with a bronze brown margin, fringe pale brown. Head black above, green in front, silvery white below. Palpi creamy white, rust-coloured towards the tips. Antennae clay-coloured with black tips. Thorax above dark green with lateral golden yellow streaks, cream-coloured below. Femora of the first pair of legs creamy, tibiae and tarsi absent, of the second and third pairs steel-coloured with a purple reflection, tibiae and tarsi of the second pair creamy, of the third purple blue with creamy bands. Abdomen dark green above and beneath, banded with three light golden yellow rings at equal distances, two indistinct coppery bands between them, one slanting yellow lateral stripe each at the base. Anal tuft brownish, white laterally. 16 mm. Santa Marta.

S. porizoniformis Wkr. Purple. Head blue above, palpi white below. Thorax with three white stripes, pectus white. Abdomen with white bands on the posterior margin of each segment, white beneath. Legs with white bands. Wings transparent. Forewing with golden yellow margins, distal area and discal band. 15 mm. Pará, Tapajoz, Villa nova.

S. chea Drc. Head, antennae, thorax, palpi, abdomen and anal tuft black. Legs yellow with black bands. Forewing and hindwing hyaline, costal margin of forewing and the veins of all the wings black. 14 mm. Amazons.

- peltastiformis*. **S. peltastiformis** Wkr. Black, head in front silvery, behind with yellow hairs, palpi dingy yellow, with black hairs at the base. Antennae club-shaped, rust-coloured, and rough below, somewhat longer than the thorax. Pectus on each side with a yellow spot in front and another one at the base of the forewing (shoulder-spot), the abdominal segments with yellow posterior margins, the anal tuft with a few yellow hairs on each side below. Femorae with yellow stripes. Anterior tibiae and tarsi dingy yellow, middle tibiae with a yellow band, hind tibiae with yellow hair at the base and end, as well as a white place below between the spurs. Wings transparent with a yellow reflection, fringes short. The 2nd interior vein of the forewing somewhat nearer to the 1st. than to the 3rd, the third nearer to the 4th than to the 2nd, the 2nd upper vein bifurcates before half of its length. 18 mm. Villa nova. Only 1 ♀ known.
- panurgiformis*. **S. panurgiformis** Wkr. Purple black. Head white and lustrous, with pale yellow hair behind. Palpi whitish, oblong, darker to the end. Antennae club-shaped, longer than the thorax, rust-coloured below, the apex remains dark. Thorax with three yellow stripes. Pectus mostly covered with yellow hair. Abdominal segments with yellow bands, beneath with a yellow streak. Anal tuft with a few yellow hairs on each side. Legs with yellow bands, hind tibiae rather thickly haired. Wings transparent, margins blackish coppery. Forewing with a blackish coppery transverse band. 16—17 mm. Pará, Santarem, Tapayoz, Villa nova. Only ♂♂ known so far.
- opiiformis*. **S. opiiformis** Wkr. Bluish black. Orbita white, palpi whitish below. Antennae very much longer than the thorax. Posterior margins of the abdominal segments whitish, anal tuft golden yellow. Legs with silvery white bands, anterior coxae silvery. Wings transparent; forewing with purple blackish fringe, costa and cross-vein. 12—14 mm. Pará. 1 ♀ known.
- le moulti*. **S. le moulti** Le Cerf is a not quite certain species which is said to be similar to *benoisti* Le Cerf and *cater-naulti* Strd. (p. 1230). Chiefly black with few white markings. South America.
- benoisti*. **S. benoisti** Le Cerf (176 d). ♂: face blackish blue, edged white before the eyes. Palpi purely white below, black above. Antennae blackish blue, with a small white preapical spot above. Collar and thorax blackish blue, with fine yellow streaks sideways, pectus below with a round whitish yellow spot on each side. Abdomen long and thin, blackish blue, the 2nd and 3rd segments edged with pale yellow; anal tuft long, blackish blue with a few white hairs laterally; ventrum white, the last segment blackish blue. Legs blackish blue and white. Forewing transparent, with black margins and veins, the distal margin and the discal vein purple black, the distal margin traversed by five veins, pale yellow between them, beneath the costal and posterior margins and the main veins are yellowish. Hindwing transparent, all the fringes bronze purple. LE CERF sees in a damaged specimen from Guiana the ♀ of *benoisti*. It is larger, the 2nd and 3rd abdominal segments edged with whitish yellow. Anal tuft white on each side, ventrum white as far as the 4th segment, the last segments black. Forewing with a broader distal margin, the distal area correspondingly smaller, almost twice higher than broad, the discal vein much thicker. ♂ 14 mm, ♀ 19 mm. French Guiana, Gourdonville; October.
- germaini*. **S. germaini** Le Cerf (176 c). ♂: head black, face white, palpi whitish yellow, antennae black above, brown below, especially before the apex. Collar and thorax blackish blue, abdomen black, the 4th segment with yellow rings, anal tuft black, with yellow traces laterally and in the middle, the 4th, 5th and 6th segments yellowish white beneath. Legs yellow and black. Forewing transparent, margins, veins and discal vein blackish blue, hindwing transparent, veins and margins black, fringes of all the wings black. ♀: separated from the ♂ by a black face, white around the eyes, the anal tuft being black only in the middle and slightly outside, only two white abdominal rings beneath, and a smaller transparent distal area. 12.5—19 mm. Brazil, Novo Friburgo, Nova Teutonia; Sa. Catharina (PLAUMANN), February.
- plagiophleps*. **S. plagiophleps** sp. n. (177 a). One of the very common South-American species which are marked bluish black and yellow and are evidently all very closely allied, as for instance *germaini* Le Cerf, *peltastiformis* Wkr., *flavipectus* Le Cerf, *flavostrigata* Le Cerf etc. The species is easily distinguished from among all the others by the discal vein of the forewing being very obliquely inclined inwards and the relatively narrow distal margin, which is broadest at the apex, getting extremely fine towards the interior angle and exhibiting no marking. Antennae and head black, white before the eyes, the palpi and collar yellow, thorax blackish blue with two distinct marginal lines. Abdomen and anal tuft black, the 1st, 2nd and 4th segment finely edged with yellow behind, quite yellow beneath. Legs predominantly yellow, the end of the tibiae above black. Forewing hyaline with the marks mentioned; hindwing hyaline, margins and veins blackish brown, fringe greyish brown. 16 to 17 mm. 1 ♂, 2 ♀♀. Bolivia, Rio Songo. — Types in the Berlin Museum.
- myrmosaepennis*. **S. myrmosaepennis** Wkr. Bluish black, face and orbita white. Palpi white, striped black. Antennae rough below, twice as long as the thorax which exhibits yellow stripes on each side. Metathorax yellow. Abdomen blackish blue, yellow on the posterior margin of each segment. Anal tuft rather long and black. Tibiae and tarsi with white bands. Wings transparent with short fringes; forewing blackish blue along the costa, the distal area as well as the spot on the discal vein likewise blackish blue. 18—20 mm. Pará. 1 ♂.
- glyptaeformis*. **S. glyptaeformis** Wkr. Purple coppery, face silvery. Palpi yellow. Antennae dark, yellow below, with

a broad yellow band in the middle. Thorax in front with a yellow marking on each side. Posterior margins of the abdominal segments and underside yellow. Anal tuft with a few yellow hairs. Legs yellow, end of the tibiae and at the joint at the tarsi purple. 13—14 mm. Villa nova. Only ♂♂.

S. croesiformis *Wkr.* Abdomen purple black, strong; face silvery. Palpi whitish with black tips, erect. *croesiformis*. Antennae longer than the thorax, rust-coloured below. Abdomen with a narrow whitish band on the posterior margin of the 4th segment. Legs dark blue, tibiae and tarsi sometimes coppery; tibiae, especially the hind tibiae, very strongly ciliated. Anal tuft interspersed with red. Wings transparent, costa and fringes coppery. ♂ 14—15 mm. Pará, Villa nova.

S. cladiiformis *Wkr.* Blackish blue, robust. Head silvery on each side and with white hair behind. *cladiiformis*. Antennae rust-coloured, black towards the end, slightly longer than the thorax. Abdomen with a white hair-tuft on each side at the base, only somewhat longer than the thorax. Anal tuft with a few white hairs. Legs strong, tibiae and tarsi whitish, lustrous below. Forewing transparent, veins black, dingy yellow from the base to the discal vein, fringe short; hindwing transparent. ♀ 14—15 mm. Santarem.

S. ceropaliformis *Wkr.* Blackish. Head white in front. Palpi not very long, whitish like the chest. *ceropaliformis*. Antennae bristle-shaped, densely pectinated. Abdomen rusty brown, anal tuft short. Legs rusty brown, anterior femora whitish, hind tibiae very thickly ciliated. Forewing transparent, rusty brown along the costa; hindwing transparent. ♂ 14—15 mm. Pará, Villa nova.

S. cerceriformis *Wkr.* Purple. Head black, face silvery, with yellowish hair behind. Palpi yellow. *cerceriformis*. Thorax blue, pectus silvery. Posterior margins of the abdominal segments yellow, anal tuft dingy yellow with a few brown hairs. Legs ochreous, coxa and femora yellow. Forewing transparent, purple along the costa, like the discal vein which is still edged with yellow, distal area with yellow streaks, fringe rather long and yellow; hindwing transparent. 15 mm. Pará.

S. panisciformis *Wkr.* Dingy yellow. Head in front white on each side, vertex dark green. Antennae black, filiform, brownish yellow and rough below. Thorax dark green. Abdomen dark green, especially at the base and towards the apex, anal tuft composed of long partly black hair. Wings transparent. Forewing with the usual transverse band and margins brownish yellow, very narrow. ♂ 18—20 mm. Valley of the Amazon R. *panisciformis*.

S. hippolyte *Drc.* (176 d). Forewing yellowish hyaline, veins black, apex and distal margin golden brown; hindwing hyaline, fringes of all the wings black. Head, thorax and abdomen black, base of thorax and anal tuft yellow. Legs black with yellow bands. Antennae black. 26 mm. Mexico, Cuernavaca, Morelos; June. *hippolyte*.

S. dinetiformis *Wkr.* Brownish yellow. Face white, palpi yellow. Antennae black, rust-coloured below. *dinetiformis*. Thorax with a black dorsal stripe, yellowish laterally, posterior margins of the abdominal segments yellow. Anal tuft moderately long. Legs yellowish. Wings transparent with a purple lustre and coppery black fringes. Forewing with a rust-coloured line above the discal vein. 16—18 mm. Pernambuco. ♂.

S. armasata *Drc.* (176 d). All the wings transparent with a yellowish reflection, the costal, distal and inner margins of the forewing scaled yellowish brown, the veins and fringes of both wings darker brown. Wings beneath light yellow. Palpi and face yellow, antennae dark brown, yellow at the base. Thorax and abdomen blackish brown with a yellow line at the base of the abdomen. Anal tuft yellowish brown. Legs orange with black bands. 37 mm. Mexico, Durango. *armasata*.

S. hermione *Drc.* (176 d). Forewing hyaline, yellowish at the inner margin, shaded, costal and distal margins yellowish brown. Hindwing hyaline, the fringes of all the wings brown. Thorax and abdomen black, collar and tegulae yellow, abdomen with yellow bands. Antennae black, broadly yellowish brown before the tips. Legs yellow with black bands. 25 mm. Mexico, Teapa, Tabasco, Atoyac, Vera Cruz; February—May. *hermione*.

S. corporalis *Meyr.* Head deep blue, orbita white, collar pale yellow. Palpi whitish. Thorax dark blue, the inner margin of the tegulae yellowish. Abdomen deep blue, the 3rd and 5th segments with indistinct yellow posterior rings, anal tuft deep purple mixed with white. Forewing hyaline, iridescent, costal margin, a moderately broad distal margin, discal vein and veins dark purple blue, anal margin with traces of yellow, fringe dark grey. Hindwing iridescent-hyaline, veins and margins black, costal margin yellow, fringe dark grey. 17 mm. Taperinha; July. ♂. *corporalis*.

S. aequalis *Wkr.* Brownish black. Eyes edged with white. Palpi yellow with a coppery brown streak outside, white below, the 3rd joint pointed, half as long as the 2nd. Antennae gradually thickening, yellow before the tips below. Thorax with a yellow spot in front, laterally striped yellow. Pectus silvery, with a yellow spot on each side. Abdomen tapering, yellow in front, with narrow yellow bands on the posterior margins of all the segments. Anal tuft greenish black, half as long as the abdomen, yellow laterally, yellow below at the end. Legs yellow. Forewing transparent, fringe purple, costa, transverse line and distal margin purple. Hindwing transparent, fringe purple. ♂ 20 mm. Pará. *aequalis*.

mardia. **S. mardia** Drc. (176 d) is allied to *tryphoniformis* Wkr. (177 b) from which it differs as follows: forewing and hindwing quite hyaline, discal spot and the spot at the apex beautifully reddish orange instead of yellowish brown. Head, thorax and abdomen black instead of yellow as in *tryphoniformis*. Anal tuft broad and bright reddish orange. Antennae black, palpi orange. 18—19 mm. Mexico: Durango.

pallene. **S. pallene** Drc. (176 d). All the wings hyaline, veins black, apex and distal margin of forewing broadly golden brown. Head, thorax and abdomen black. Collar, base of thorax and the last abdominal segment orange. Underside of the head, thorax and abdomen yellowish brown. Legs and antennae black, the antennae white near the tips. 13 mm. Mexico: Teapa, Tabasco; March, April.

tryphoniformis. **S. tryphoniformis** Wkr. (177 b). ♂: coppery black, face silvery white, palpi yellow. Antennae black, dark rust-coloured below. Thorax with four yellow stripes, the sides and pectus yellow. Abdomen compressed at the base, the posterior margins of the segments whitish, yellowish laterally, white beneath. Anal tuft rather long with a few dingy yellow hairs. Legs dingy yellow, femora black above, tibiae black at the base. Wings transparent, iridescent, fringes coppery and very short. The doubtful ♀ shows the antennae scaled below at the base. Posterior margins of the segments dingy yellow. Legs pale dingy yellow, tibiae partly brownish at the ends. Wings with longer fringes. Forewing purple with dingy yellow streaks in the distal area and a yellow streak right across the discal vein. 20 mm. Pará: Villa nova. — According to BUTLER it is said to be synonymous with the following *ischniformis* Wkr. and *plectisciformis* Wkr.

plectisciformis. **S. plectisciformis** Wkr. ♂: purple. Head green, face white. Palpi yellow. Antennae black, rust-coloured below. Thorax with two yellow stripes on each side. Abdomen with a yellow band on the posterior margin of each segment. Anal tuft with very few yellowish hairs. Legs dingy yellow, striped black. Wings transparent, fringes very short. Forewing purple with a yellow streak along the costa, distal area striated yellow, discal vein purple. 18 mm. Pará.

ischniformis. **S. ischniformis** Wkr. ♂: purple. Face and orbita white. Head yellow behind. Palpi yellow, strongly haired. Antennae slender, very much longer than the blue thorax. Abdomen with yellow bands on the posterior margins of the segments. Underside and anal tuft below yellow. Legs yellowish, anterior coxae white, hind tibiae and joints on the posterior tarsi with purple bands. Wings transparent, forewing with purple golden margins, distal area and discal vein! 12—13 mm. Pará.

santanna. **S. santanna** Kaye (177 b). (Described as *Aegeria*.) Collar white. Head and thorax bronze blue with two narrow yellow segmental bands (not discernible on the figure). Legs bronze blue, with narrow yellow bands. Forewing beyond the cell, thus the whole distal area, entirely bronze blue, also along the costa; discoidal vein darker blue. Hindwing transparent with narrow black margins. 19 mm. — The species is well discernible from other *Synanthedon*-species by the completely dusted distal area. Trinidad, St. Ann's; December.

martenii. **S. martenii** sp. nov. (176 f) is somewhat similar to *pallene* Drc. (176 d). Antennae, head, thorax and abdomen blackish blue. Palpi yellow, white before the eyes. Thorax with two yellow lateral stripes. Abdomen with traces of yellow rings on the posterior segmental margins, anal tuft black. Pectus yellow, ventrum distinctly belted yellow, anal tuft yellow below. Legs blackish above, yellow beneath. Forewing transparent, costal vein, margins, the broad discal vein and the veins black. A narrow distal area, higher than broad, remains transparent, behind it towards the distal margin a beautifully copper-red band which is only bordered by the black distal margin and traversed by 5 black veins. Hindwing transparent, veins and margins black. The rather long fringes of all the wings greyish brown, the anal region of the hindwing hairless. 20 mm. Brazil, Rio de Janeiro? October. Type in the Coll. MARTEN.

tetranoma. **S. tetranoma** Meyr. Head dark purple reddish, in front and the collar orange, face whitish. Palpi orange, black at the base. Antennae black, dingy yellow below. Thorax bluish black, median line, margins of the tegulae, posterior margin and pectus orange. Abdomen bluish black, segments 1—4 with narrow orange posterior rings. Ventrums orange. Anal tuft broad, dark blue, white above, mixed with yellow on the sides. Legs quite orange. Forewing iridescent hyaline, anal margin yellowish, veins and costal margin dark brown beyond the cell, red lines at the basal part on 12 and between 9 and 10, cross-vein edged with red, a narrow reddish distal band, the veins in it thickly black. Hindwing hyaline, veins and margin dark brown. 23 mm. Peru: Iquitos; March. 1 ♂.

sallustiformis. **S. sallustiformis** Drc. (176 e). Forewing whitish hyaline, costal margin, apex and veins black, hindwing hyaline, fringe and veins black. Head, antennae, thorax and abdomen bluish black, the abdomen with yellow bands, anal tuft brownish at the apex. Palpi white below, black above. Tarsi with white bands. 17 mm. Mexico: Coatepec; Panama. Bugaba. 300—500 m.

producta. **S. producta** Wkr. (177 h). Forewing hyaline, costal margin, apex, discal mark and veins black. Hindwing hyaline, fringe and veins black. Head, antennae and thorax bluish black. Abdomen bluish black, all the

segments finely edged with yellow, a strong black anal tuft. Legs black. tarsi with white bands. 15 mm. Mexico: Oaxaca; Panama, Bugaba.

S. anthracipennis Bsd. Head and antennae black. Palpi yellow beneath, the last joint black at the apex. Abdomen and legs brownish black, abdomen with 4 yellow rings, anal tuft black, with few yellow hairs laterally. Forewing brown with a small orange spot at the cross-vein or beyond it. Hindwing transparent with broad black margins and veins. Georgia. It is said to live on a species of willow and to look like *S. asiliformis*. — It belongs to the doubtful species which, as BEUTENMÜLLER already regretted in 1894 (in Bull. Americ. Mus. Nat. Hist.), have never been discovered again; ENGELHARDT likewise deals with the species in Bull. Brookl. Ent. Soc. 1928 and promises a publication at a later period. He succeeded, however, in clearing up the synonymy of BOISDUVAL's *S. bibionipennis chrysidipennis* as *rutilans* Hy. Edw. and *nomadaepennis* as *Memythrus* (Albana) *pyramidalis* Wkr.

S. fasciculipes Wkr. Jet-black. Head silvery white behind, eye-rings the same. Palpi erect, silvery white below. Antennae short and delicate. Pectus silvery. Abdomen pointed, anal tuft deep coppery. Legs slender, tibiae densely haired on their whole length, especially the posterior pair, tarsi silvery white basad. Wings transparent, veins and fringes black. Forewing with a black line right across the end of the discal vein. 15—16 mm. Ega.

S. fulvopyga Le Cerf. All the wings hyaline, veins and margins black with a bluish green reflection, distal area crossed by four veins. Hindwing hyaline, the veins, margins and fringes of all the wings black. Head black with short whitish hairs at the margin, orbita white. Palpi, antennae, thorax, abdomen and legs black with a bluish green reflection. Anal tuft pale yellow. 24 mm. Brazil. 1 ♀.

S. flavostrigata Le Cerf (176 e). Head blackish blue, neck yellow. Face white, with bronze scales above. Palpi yellow, with a short black line outside on the 2nd and 3rd joints. Antennae blackish blue, white above before the tips, brown below, yellow at the base. Collar purple black. Thorax blackish blue, laterally with yellow stripes, its posterior margin with yellow hair, scaled yellowish below. Abdomen black, scantily strewn with yellowish white, all the segments finely edged with yellow, the 7th broadest. Anal tuft black, yellow in the middle and on the sides. Ventrums black, almost entirely scaled yellow. Legs black and yellow. Forewing transparent, margins and veins black, the distal margin between the veins 3 and 8 scaled yellow, the outside of the discocellular vein slightly yellow. Beneath almost entirely yellow excepting the veins. Hindwing transparent, veins, margins and fringes black. 15—16 mm. Mexico: Tabasco.

S. tipuliformis Clerck (Vol. 2, pl. 51 d). Head purple black, orbita white. Palpi yellow below, black above. Antennae black, yellow below like the collar, too. Thorax blackish brown with a narrow yellow streak on each side, yellow below. Abdomen purple black with narrow yellow rings on the 2nd, 4th and the two last segments. Anal tuft black. Legs blackish with two yellow bands on the tibiae, tarsi yellow. Forewing transparent with golden purple margins, the broad distal margin with golden yellow streaks between the veins. Cross-vein strong, brownish black. Hindwing transparent, narrowly margined. 15—22 mm. North America, Australia, New Zealand, Europe, and Asia. A very common and well known species, everywhere imported with the currant and gooseberry from the Old World, in which way it also came to America. The larva lives in the plants mentioned, hibernating in their twigs until May; imago from the end of May to July.

S. flava Hy. Edw. is said to be *S. tipuliformis*. Panama: Colon. *flava*.

S. laticincta Burm. Wings transparent, forewing with a broad black distal margin, the other margins narrower, discal vein feeble. Palpi, thoracic sides, metathorax, the 1st, 5th and 6th rings of the otherwise black abdomen bright yellow. Anal tuft yellow. Legs black, the joints of the forelegs and hindlegs and a great part of the hindlegs yellow. Tarsi at the base and the inner margin of the hindwing yellow. 15 mm. Rio de Janeiro.

S. albicalcarata Burm. Ground-colour black, wings transparent, margins and cross-vein thin and black. Metathorax and the 1st and 2nd rings of the abdomen yellow, warming into whitish. Legs black, the spurs of the middle and hind legs black, of the forelegs white. Tarsal joints black and white, femora yellow. The 3rd abdominal segment white beneath, palpal tips white, too. Antennae brownish 15—20 mm. Buenos Aires. *albicalcarata*.

S. albociliata Engelh. Antennae absent, those of the ♀ are black. Palpi black above, snow-white below, the coxae of the forelegs snow-white. Thorax black with two narrow yellowish white lateral stripes, with rough hair in the ♂. Abdomen black, the 4th segment above, the 4th, 5th and 6th beneath yellowish white. Anal tuft black, mixed with white in the ♂ beneath. Legs black and white, with rough hair. The broad costa and the discal mark black like the veins, fringe whitish. Hindwing transparent, the veins and the narrow margin black, fringe white. The ♀ shows almost entirely black forewings, whitish along the inner margin and before the discal mark. Hindwing transparent with a broader black margin. 18—20 mm. Kerrville, Texas; October. — ENGELHARDT presumes the food-plant to be a species of Eupatoria. *albociliata*.

S. auritincta Engelh. ♂: antennae black, white near the apex. Palpi black above, yellow below, the last joint here also black. Head black, white around the eyes. Collar golden yellow above, white on the sides

and below. Thorax black with two broad lateral stripes, golden yellow behind. Coxae of forelegs white, middle and hindlegs violettish black with white rings and spurs. Forewing transparent, costa, the broad apical margin and the broad discal vein black, fringe dull black. Hindwing transparent, veins, fringe black, whitish at the base. Abdomen black, the 2nd, 3rd, 4th, 6th and 7th segments narrowly yellow. Anal tuft steel-blue, laterally white. The 1st and 2nd segments beneath with white scales, a narrow band on the 4th and 5th, and lateral spots on the 7th. 14—15 mm. ♀: antennae black, the tips more rarely white. Palpi golden yellow above, pale yellow below. The middle and hind legs golden yellow with violettish black markings. Forewing like that of the ♂, but marked yellow in the apical area, the discal mark outside also yellow. Hindwing like that of the ♂, yellowish at the base. Abdomen violettish black with narrow yellow rings on all the segments, except on the 5th and 7th which are quite yellow. Beneath intensely scaled yellow. Anal tuft golden yellow with a black base and black sides. 12—21 mm. Arizona; August.

arizonae. **S. arizonae** *Bent.* (177 b). Head black, orbita white. Palpi yellow. Collar edged with yellow. Antennae black. Thorax black with a yellow streak on each side and a strong posterior transverse streak, beneath likewise yellow on each side. Abdomen black with narrow yellow bands on the 1st, 2nd, 3rd, 5th and 6th segments, the 4th very broadly yellow. Anal tuft yellow, laterally black. Legs yellow, tibiae with black bands. Forewing transparent, the costal margin and fringe blackish, the inner margin, cross-vein and distal margin beautifully golden orange, veins black. The under surface with still more orange. Hindwing transparent with a narrow margin, partly orange at the apex, fringe brown. 23 mm. Arizona, Texas. Only ♀♀ are known so far, the ♂♂ and the early stages are unknown.

morula. **S. morula** *Hy. Edw.* (177 b). Head and antennae black. Palpi dingy white. Thorax brownish black with a very narrow white lateral line. Abdomen deep brownish black with a narrow dingy white band on the 2nd, 4th, and the two last segments. Anal tuft black, impurely white beneath. Legs black, spurs, and tarsi beneath white. Forewing, veins and cross-vein broadly black, the transparent places slightly scaled white, white beneath, the rest black. Hindwing transparent with a narrow black margin. 20 mm. Texas.

novaroënsis. **S. novaroënsis** *Hy. Edw.* (177 c). Head, palpi and collar beautifully reddish orange, antennae black. Thorax black, patagia and a round spot at the anal margin beautifully reddish orange, thorax beneath quite orange. Legs orange with black bands. Forewing transparent with bluish black margins and a strong cross-vein, beneath orange at the base. Hindwing transparent with narrow bluish black margins. 30—35 mm. This pretty species has been found so far only in California and Washington.

brunneri. **S. brunneri** *Busck.* is very closely allied with *S. novaroënsis* (177 c), but distinguished by the somewhat more slender shape, the blue ground-colour and less red on the abdomen. Palpi reddish orange with a broad black exterior streak. Face dark metallic blue. Head black, antennae bluish black. Thorax bluish black, speckled red in front, patagia dark reddish orange. Forewing transparent in both sexes with broad purple blue margins and a broad transverse streak at the end of the cell, a narrow orange costal margin, the apical and especially the costal margins beneath strewn with reddish orange. Hindwing transparent with narrow blackish blue margins and veins, the costal margin here also red, especially beneath. Abdomen dark metallic blue with distinct red transverse streaks on the 2nd and 4th segments and sometimes with red traces on the other segments. Anal tuft black in the middle, brick-red laterally and below. Legs dark blue with red bands and spots, tarsi blue. 24—27 mm. The larva lives in *Pinus ponderosa*. Camas, Montana.

laeta. **S. laeta** *Wkr.* (176 e). Deep black. Palpi strong. Antennae plain, almost twice as long as the thorax, with black tips, before them almost to the middle white. Thorax with white lateral stripes, pectus white. Abdomen red with black dorsal spots occupying the whole surface towards the base, each of them containing a white spot. Legs white, femora and tibial tips bluish black. Wings transparent with short black fringes. Forewing with a coppery black distal area and a black streak across to the end of the discal vein. 20—22 mm.

hemigymna. **S. hemigymna** *sp. n.* (176 e). Antennae terminating pointed, scarcely thickened before the ends, black. Head and thorax black, the anterior edge dusted dull yellow. Abdomen delicate and narrow, thinnest in the middle, the 1st, 2nd 3rd segments black, the 4th laterally yellow, the following segments greyish yellow. Anal tuft strong, bluish violet above in the middle, the margins and especially the sides and below deep reddish orange, which colour is slightly continued beneath on the 6th and 5th segments. The rest of the under surface whitish, the 3rd segment darker. Femora black, tibiae bright yellow, the posterior ones black before the end, tarsi black. All the wings brownish yellow hyaline, the costal margin intensely brownish, the forewing with a brown discal vein, brown narrow margins and veins, a black base, slightly yellow behind it. A very beautiful species, apparently allied with *S. laeta* *Wkr.* 29 mm. Brazil, Itatiaia. 1 ♂, flying in the sunshine on a forest-glade. Type: Coll. MARTEN.

rubrofascia. **S. rubrofascia** *Hy. Edw.* (177 c). Head, palpi, antennae and thorax black, with a metallic gloss. Abdomen black, the 4th and 5th segments quite red. Anal tuft black. Legs black, tarsi dingy white. Forewing transparent, the costal and inner margins and the cross-vein narrowly, the distal margin very broadly black. The cross-vein is remarkably long, widening at its termination into the costa. Hindwing transparent with very narrow purple brown margins. 20 mm. Only known from Georgia.

S. rubricincta *Beut.* Head bluish black. Collar black, orange in front. Palpi orange, the last joint above *rubricincta*. black. Antennae bluish black. Thorax greenish black or bluish black, metallic. Patagia with reddish orange hair. Abdomen black, bright red along the sides. Anal tuft metallic greenish black, red in the middle. Thorax orange below. The 1st and 2nd joints of the abdomen beneath bluish black, the others red. Legs steel-blue. Forewing bluish black, purple outside, red between the veins, fringe brown, basal area narrowly transparent, the transparent distal area likewise small, discoidal vein purple with a broad red streak. base of the wing red. Hindwing transparent, distal margin narrow, purple, fringe brown. Forewing beneath less distinctly marked, with an orange costa. 17.5 mm. Cochise County, Arizona; August.

S. bolteri *Hy. Edw.* (= *rubrofascia Beut. nec Hy. Edw.*) (177 c). Head and thorax from deep steel- *bolteri*. blue to blackish, orbita white. Palpi above black, orange below. Antennae black, the last third before the apex yellowish. Abdomen blackish steel-blue, the 4th and 5th segments above and beneath broadly scarlet, also the 6th in the ♀ beneath. Anal tuft black with some white. Legs bluish black, tibiae with whitish hair-tufts, tarsi pale yellow. Forewing transparent, the costal and inner margins the same, the cross-vein blackish blue, distal area broadly scarlet or copper-red, veins black, fringe violettish brown. Hindwing transparent with a narrow black margin, fringe violettish brown. 12—20 mm. New York, New Jersey, Illinois, Manitoba. Larva in branches of willow. — Apparently closely allied to the palaearctic *S. formicaeformis*.

S. buprestiformis *Wkr.* Blue, head in front white on each side, palpi black, rather long, hairy, antennae *buprestiformis*. black. Thorax with a red streak on each side, pectus beneath also spotted red. Abdomen with a broad red band at the base. Legs black, woolly below, white. Forewing purple red with a transparent basal streak and a broad-golden yellow subapical band. Hindwing transparent with purple red margins. 22 mm. Amazon Valley. 1 ♀.

S. fulvipes *Harris* (177 c). Head, antennae, thorax and abdomen deep black with a metallic blue re- *fulvipes*. flection. Palpi reddish orange below, black above. The 1st, 2nd and 3rd segments of the abdomen beneath orange. Legs beautifully orange, femora bluish black. Thorax below with a large orange spot on each side. Forewing transparent with narrow deep bluish black margins, discal mark narrow, bluish black, outwards with a small orange spot, inwards with a small dentiform projection, as in some tropical species of *Melittia*, the base of the wing with little orange. Forewing beneath slightly orange at the costa and inner margin. Hindwing transparent, margins narrow, bluish black. 22 mm. Canada, New England States.

S. saxifragae *Hy. Edw.* (= *henshawii Hy. Edw.*) (177 c) is allied to *fulvipes*. Also quite black, no orange *saxifragae*. on the abdomen beneath. Palpi orange, tips black, in the ♀ black above, yellow below. Thorax yellow beneath on both sides, legs as in *fulvipes*. Forewing transparent, with bluish black or violettish black margins. costal and inner margins narrow, cross-vein strong, distal margin broad. The base of the wing and the outside of the discal mark orange. Hindwing transparent with narrow bluish black or violettish black margins. 18—23 mm. Labrador. Colorado.

S. castaneae *Busck* (177 c). Palpi yellow below, black above strewn with yellow scales, the terminal *castaneae*. half of the 3rd joint quite black. Antennae black with reddish bronze tips. Face bluish black, broadly white before the eyes. Head black, thorax metallic bluish black with two narrow yellow lateral stripes, in the ♀ also with a narrow yellow posterior margin. Forewing transparent in both sexes, veins bluish black mixed with yellow scales, fringe bluish black. Hindwing transparent, veins black, costal margin yellow, fringe bluish black. Abdomen deep bluish black with a yellow semi-ring on the 4th segment beneath, the ♀ also with narrow yellow 3rd and 4th segments above. The end of the abdomen laterally yellow. Legs bluish black with narrow yellow rings at the ends of the different joints. Tarsi of the ♀ dusted yellow, tibiae of the hindlegs with a pale yellow ring near the tarsi. Lynchburg, Virginia, and Snow shoe, Pennsylvania. Bred from chestnuts. April, May.

S. pictipes *Grt. & Rob.* (= *inuitata Hy. Edw.*). Head bluish black, sometimes with a few yellow hairs *pictipes*. between the antennae. Palpi pale yellow, black above. Collar somewhat yellow on the sides. Thorax bluish black with a narrow pale yellow line on each side. Abdomen bluish black with a very narrow pale yellow ring on the 2nd and 4th segments, closing beneath. Anal tuft pointed, bluish black, laterally white. Legs bluish black with narrow yellow hair-tufts on the tibiae and two yellow rings, one near the tarsi and one at the second middle pair of spurs, tarsi with yellow rings, anterior coxae yellow. Forewing transparent with narrow bluish black margins, cross-vein somewhat broader. Sometimes the inner margin is slightly scaled yellow. On the under surface the costal and distal margins and the cross-vein are yellowish. Hindwing transparent with narrow black margins, fringe the same, somewhat whitish towards the base. 15—26 mm. Canada to Florida and Texas, westward as far as the Pacific. The larva lives beneath the bark (trunk and stronger twigs) of plums, cherries, peaches, chestnuts and *Amelanchier canadensis* until the beginning of June. Imago June till July.

S. viburni *Engelk.* Antennae black, in the ♀ whitish yellow before the tips. Palpi black above, yellow *viburni*. below. Head black, always yellowish between the eyes and behind. All the wings transparent, more broadly margined in the ♀ and mixed with yellowish, otherwise very similar to *S. pictipes*. Abdomen black, the 2nd seg-

ment above narrowly pale yellow, a pale yellow spot on each side of the 4th segment, pale yellow scales on the 2nd and 3rd segments above in the ♀. 19—20 mm. Long Island, Brooklyn, but it is surely farther distributed. The larva lives in trunks and twigs, generally in damaged places, of *Viburnum dentatum*, but also of cultivated species of the genus *Viburnum*, for instance in gardens and parks of Brooklyn. The cocoon is made of particles of wood underneath the bark, the imago leaving it in May or June. According to ENGELHARDT, the larva lives for a year and has much to suffer from parasites.

albicornis. **S. albicornis** Hy. Edw. (= *proxima* Hy. Edw.) (176 e ♀, 178 a ♂). Head black, palpi whitish yellow. Antennae bluish black, little white before the tips in the ♂, extensively white in the ♀. Thorax black with a pale yellow stripe on each side, which, however, may also be absent, a pale yellow spot beneath on each side. Abdomen blackish bronze. Anal tuft white below. Legs bluish black, tibiae with white hair-tufts, anterior coxae purely white. Forewing transparent with violettish brown margins, the costal and inner margins narrow and black, distal margin broad, golden yellow between the veins. Cross-vein distinct, bluish black. Beneath the costal margin and the cross-vein are yellowish. Hindwing transparent with narrow blackish distal margins. 15—22 mm. New York, New Jersey, Pennsylvania, New Hampshire, Illinois, Colorado, California, Nevada, Oregon. — A very common species appearing in May and June, its larva living in trunks and twigs of young willows in swampy places.

acerni. **S. acerni** Clem. (= *acericolum* Germ.) (176 e). Head, collar and palpi orange, orbita white. Antennae brownish black. Thorax yellow above and below. Abdomen bluish black, more or less covered with yellow scales. Under surface quite yellow. Anal tuft orange. Legs pale yellow, tibiae with a black band at the end. Forewing narrow with narrow purple brown margins, more or less scaled yellow. Distal part of forewing pale yellow, veins black, a broad black cross-vein. Hindwing transparent with very narrow margins and purple brown fringe, sometimes yellow at the apex. 22—25 mm. Canada, New England, Central States, to the west as far as Nebraska. — One of the commonest species, appearing in May and June. The larva lives in various species of maple, e. g. *Acer dysocarpum*, *Acer rubrum*, *sacharinum*, as well as in *Pyrus americana*, in trunks and twigs, and it often does so much harm that younger trees may decay. According to HULST, the eggs are deposited at night!

accerubi. **S. accerubi** Engelh. Antennae black, whitish yellow before the tips, especially in the ♀, palpi orange, black apically, head black, orbita silvery white. Collar orange, mixed with black, thorax violettish black above, pale yellow beneath, patagia broadly edged with yellow. The coxae of the forelegs are silvery white. All the wings transparent, veins, costa, a rather broad apical margin and discal mark on the forewing black; beneath the same, with a yellowish tinge. Abdomen steel-blue or violettish blue, in the ♂ the segments 2, 4, 5, 6 are narrowly margined with whitish, almost pale yellow, in the ♀ only the segments 4, 5 and 6, the same segments beneath quite pale yellow, anal tuft bright red, mixed with black in the ♂. Legs bluish black, mixed with yellow. 18—20 mm. North Atlantic and Central Western States, especially found by ENGELHARDT near New York and Long Island. — The larva lives underneath the bark of different species of maple, sometimes in deserted passages of *Zeuzera pyrina*, but also like *Syn. acerni* Clem. It pupates in May in an oblong cocoon from which the imago generally emerges in June or July.

aureopurpurea. **S. aureopurpurea** Hy. Edw. (176 f). Head purple brown, palpi yellow, black in front. Collar narrowly edged with yellow. Antennae black with a broad white spot before the tip. Thorax purple brown with a narrow yellow streak on the shoulders. Abdomen black with yellow rings on the 2nd, 3rd, 5th and last segments. Anal tuft black. Legs brownish black, tarsi yellowish, anterior coxae yellow. Forewing purple brown with a golden yellow reflection. Distal part with fine yellow streaks between the veins. Hindwing transparent with purple brown veins and margins. 14 mm. Texas.

tucumana. **S. tucumana** Le Cerf. Forewing transparent, discocellular, veins and margins greyish black, distal margin between the veins grey. Hindwing transparent, veins and margins black, fringe black. Head and antennae black. Palpi black and white. Thorax greyish black, with a yellow longitudinal spot on each side, a few white scales at the base of the wings and two yellow spots on the metathorax. Abdomen greyish black with yellowish margins on the segments 2 above, 4, 5 and 6 above and beneath. Anal tuft black, white laterally. Legs smoky black, tibiae with whitish yellow rings, tibial spurs white. 14 mm. 1 ♂. Tucuman, Argentina; December.

macropyga. **S. macropyga** Le Cerf is a very small species with an expanse of but 11.2 mm, especially distinguished by an enormously long anal tuft which is almost as long as the abdomen and covers the valves. Forewing transparent, the margins and veins purple black, a few yellow scales at the apex at veins 5 and 6, also at the exterior edge of the discocellular vein, the distal area is traversed by 5 veins. Hindwing transparent, veins and margins black, fringes of all the wings black. Head black, snow-white in front. Palpi quite yellow. Antennae black, finely ciliated. Thorax convex, blackish blue with light yellow lateral spots. Legs black and whitish, tibial spurs white. Abdomen blackish blue, with a blurred yellow lateral line, the 4th segment above margined with yellowish, the segments 2, 5 and 6 with yellow traces. Segments 4, 5, 6 and 7 beneath all white. The abdomen is narrow and compressed towards the end, and becomes then very broad again owing to the enormously developed anal tuft. Brazil, Fazenda do Sobrado on the Rio das Pedras, Serra da Mantagueira, 1000 m; March.

S. pyri Harris (= *koebelei* Hy. Edw.) (176 f). Head and palpi above black, below yellow. Collar above *pyri*. black, below white. Thorax black, with a yellow spot on each side below. Abdomen black with a narrow yellow ring on the 2nd and 4th segments in the ♂. the ♀ shows an almost entirely yellow 4th segment, yellow lateral streaks on the 1st and 2nd segments. Abdomen beneath longitudinally striped yellow in the middle, anal tuft black in the ♂, laterally yellow in the ♀, black in the middle. Legs black, yellowish inside, tibiae and tarsi with yellow rings, anterior coxae yellow. Antennae black, in the ♂ rarely, in the ♀ always, with a strong white spot before the apex. Forewing transparent, margins black, the costal and inner margins narrow, the distal margin broad, with yellow streaks in the ♀, cross-vein strong, under surface yellow along the costa and the inner margin. Hindwing transparent with narrow dark margins. 14—18 mm. From Canada to Florida and Texas. — The species is everywhere common; the larva lives beneath the bark of apple and pear trees. The imago appears in June and July.

S. rhododendri Benth. is allied to *pyri* and *scitula* (176 f) from which it chiefly differs in the absence of *rhododendri*. the yellow markings on the thorax which is metallic bluish black in *rhododendri*. Abdomen black with a narrow yellow band of the 2nd, 4th and 5th segments and a yellow line on each side from the base to the first yellow band. The 4th and 5th segments beneath almost entirely yellow. 10—15 mm. Cheltenham, Pennsylvania. imported in parks by the food-plant, as observed in New York and Brooklyn. Larva in twigs and trunks of *Rhododendron*, but occasionally also in mountain-laurel and *Azaleae*, living one year and pupating in a light web in wood, the imago leaving it from the middle of May until June.

S. scitula Harris (= *gallivora* Ww., *hospes* Walsh, *aemula* Hy. Edw.) (176 f). Head and antennae black. *scitula*. Palpi yellow with black tips, quite yellow in the ♀. Orbita white. Thorax deep bluish black with yellow lateral lines, and a yellow spot below on each side. Abdomen deep bluish black with a narrow yellow ring on the 2nd and 4th segments, the latter being quite yellow beneath, the 5th and 6th of the ♀ also yellow beneath. Anal tuft black, laterally yellow in the ♀. Femora bluish black, tibiae yellow with a blackish band on the otherwise yellow middle and posterior femora, anterior coxae yellow. Forewing transparent, margins and cross-vein bluish black, narrow, distal margin broad with yellow stripes between the veins. Hindwing transparent, veins and the narrow margins bluish black. 18—22 mm. Canada, New England and Central States as far as Virginia, to the west as far as Ohio and Illinois. May, June. The larva lives beneath the bark of oak, chestnut, but especially of the cornel-tree, also found in hickory and willows.

S. ithacae Benth. (177 d). Similar to *S. pyri*, but the margins of the wings and the abdomen are quite *ithacae*. black, only the palpi yellow below. Collar narrowly yellow, thorax below on each side with a small yellow spot. The ♀ has much broader margins of the wings than the ♂. 15—18 mm. New York (Ithaca).

S. corusca Hy. Edw. (177 d) is likewise a small species. Head bluish black, face and palpi yellow. Thorax *corusca*. bronze coloured with yellow stripes on each side and a posterior yellow transverse streak. Abdomen bronze coloured with narrow rings on the 1st, 2nd, 4th and last segments. Anal tuft like the abdomen, laterally sometimes yellowish. Legs outside bronze coloured, inside yellow, anterior coxae yellow. All the wings transparent with narrow golden bronze margins. 19—21 mm. Texas.

S. decipiens Hy. Edw. (= *imperfecta* Hy. Edw., *nicotianae* Hy. Edw.) (177 d). ♂: head black, orbita *decipiens*. white. Palpi yellow, black outside at the base. Collar yellow. Thorax black, with a yellow transverse streak behind, beneath with a yellow spot on each side. Abdomen mostly thick in the middle, black with yellow rings on the 2nd, 4th and last two segments, the ring on the 4th being twice as broad as the others, extending also to the under surface. Anal tuft pointed, black, yellow above on each side. Legs yellow and black, hind tibiae yellow with a broad black band. Forewing transparent, veins and margins black, distal margin with yellow streaks between the veins, the cross-vein orange or red, also the base of the wing red. Hindwing transparent with narrow brownish bronze margins and fringe, cross-vein very narrow, yellow or orange. ♀: separated from the ♂ by broader margins on the forewing, the abdomen with three bands on the 2nd, 4th and last segments, also here the middle one being the broadest, anal tuft broad, like a brush. 13—15 mm. This little species was found in Colorado and Texas; May, June till July. Larva according to HEINRICH in the galls of crippled white oaks, the habits similar to those of *S. scitula* Harris.

S. rubristigma Kell. (177 d). Head bluish black, orbita silvery white. Basal joint of palpi black, the *rubristigma*. 2nd segment black excepting the end, the 3rd quite yellow. Antennae black, collar yellow. Thorax black with a yellow transverse streak behind and below and a yellow spot on each side. Abdomen black with narrow yellow bands on the 2nd and last segments, and a broad one all around the 4th segment; the 1st segment on each side with yellow spots. Legs as in *decipiens*. Forewing transparent, cross-vein quadrangular, beautifully red, the purple brown margins very narrow. Hindwing like that of *decipiens* to which the species is closely allied. The ♀ has also broader margins. 16—18 mm. Ohio, Iowa, New York. The larva lives in galls of *Andricus cornigerus* on *Quercus palustris*. The imago in June till July.

S. prosopis Hy. Edw. (177 d). Head, antennae, thorax quite black, abdomen the same or with a narrow *prosopis*. white band on the 2nd and last segments. Palpi white, 3rd joint black. Legs black, hind tibiae with tufts and spurs white, hind tarsi with white bands, anterior coxae white. Forewing transparent, margins and cross-vein

black. Hindwing transparent with a black margin and white fringe. 14 mm. The species is easily discernible as it is quite black, except the light parts mentioned. Arizona, Fort Grant. Only ♂♂ are known; from galls of the Anime tree (Mesquite).

querci. **S. querci** Hy. Edw. (= *quercus* Hy. Edw.) (177 d). Head black. Palpi black, white at the tips and inside. Collar yellow. Antennae black. Thorax black, patagia with a few yellow scales, behind with a narrow yellow spot, beneath spotted yellow. Abdomen deep black with a very narrow yellow band on the 2nd and 3rd segments, a very broad one all around the 4th and very narrow ones again on the two last segments. Anal tuft black, broadly yellow above. Legs black, hair-tufts and spurs white, anterior coxae white with a yellow line. Forewing transparent with very narrow golden brown margins, cross-vein narrow, pale yellow. Beneath the margins and the cross-vein pale yellow. Hindwing transparent with very narrow purple brown margins, costal margin pale yellow. 12—18 mm. Arizona, Fort Grant. The larva is said to live in galls of oak.

tecta. **S. tecta** Hy. Edw. (177 d ♂, 177 e ♀). Head black, palpi yellow, collar in front narrowly yellow. Antennae black. Thorax black, with a yellow line on each side and an indistinct posterior cross-bar in yellow. Abdomen black with five yellow bands, narrow on the 1st, 2nd and the two last segments, very broad on the 4th segment. The last three rings extend to the under surface with an additional one on the 5th segment beneath. Anal tuft black, yellow beneath in the middle. Legs black, anterior coxae yellow, femora black, tibiae and tarsi with yellow rings. Forewing transparent with narrow black margins and cross-vein which is orange outside. Under surface marked yellow. Hindwing transparent with very narrow black margins. The ♀ has one ring less and the distal area of the forewing marked yellow between the veins. 18 mm. Arizona and New Jersey; specimens from the latter habitat are somewhat different. The early stages are not known.

candescens. **S. candescens** Hy. Edw. (177 e). Head blackish brown. Collar, palpi and orbita purely white. Antennae black. Thorax and abdomen blackish brown, the latter with rather broad white rings on all the segments. Anal tuft black. Legs blackish brown with golden yellow scales, the tarsi with indistinct black bands, the anterior coxae white outside. Forewing purple brown with broad margins, so that only narrow hyaline areas remain, the distal area traversed by four veins, the inner margin dusted with white, the cross-vein purple brown, reddish orange outside. Hindwing transparent with a narrow purple brown margin. 15 mm. Arizona. Only a ♂ is stated to be known, but in BEUTENMÜLLER's Monograph of the Sesiidae (Mem. Amer. Mus. Nat. Hist.) there is 1 ♀ figured, which also corresponds with the description.

sigmoidea. **S. sigmoidea** Hy. Edw. (177 e). Head and antennae purple black. Palpi yellow, black above. Collar yellow. Thorax purple black with a yellow posterior streak, under surface with a yellow spot on each side. Abdomen bluish black with a lemon-coloured band on the 2nd, 4th and last segments, the 4th extending around the whole abdomen. Anal tuft black, whitish outside. Legs bluish black, tibiae with a broad yellow band, tarsi partly yellow. Cross-vein bluish black with an orange spot outside, the broad distal margin is lighter between the veins. Hindwing transparent with very narrow black margins. 18—21 mm. New Hampshire, Massachusetts. The species is allied to the palaearctic *S. vespiiformis* (Vol. II, pl. 51 e). The larva is said to live in willows.

tacoma. **S. tacoma** Beut. (177 e). ♂: head deep black, palpi yellow above, with long black hair below. Collar narrowly yellow in front. Thorax deep black with a narrow yellow stripe on the patagia, and a narrow yellow transverse line on the posterior part, beneath with a yellow spot on each side. Abdomen deep black with narrow yellow rings behind on the 2nd, 4th, 6th and 7th segments, the last three extending all round. Anal tuft black, yellow below in the middle. Femora black, tibiae black with a yellow ring in the middle, tarsi yellow, anterior coxae with a yellow line. Forewing transparent, margins brownish black, rather broad, all reddish orange inwards, cross-vein black, reddish orange on each side. Under surface: margins and cross-vein quite reddish orange. Hindwing transparent, the margin, fringe and veins brownish black, under surface with an orange line before the dark margin, veins orange. ♀: head and abdomen as in the ♂, only with three yellow rings, on the 2nd, 4th and 6th segments. Palpi quite yellow. Forewing with very narrow brownish black margins, the reddish orange broader than in the ♂, so that the wings almost look red. Hindwing transparent, the veins and a narrow line before the brownish black margin reddish orange. Under surface with broad reddish orange margins, the fringe brownish black. 20—22 mm. Big Horn Mts., Wyoming. Mt. Ranier, 2100 m. Washington. Allied to the palaearctic *P. chrysidiformis* (Vol. II, pl. 52 d).

americana. **S. americana** Beut. (= *culiciformis* Beut.) (177 e). Head deep bluish black, orbita white. Palpi black above, orange below. Thorax and abdomen metallic bluish black, the thorax with an orange spot on each side, below, the abdomen with the whole fourth segment light red, sometimes with a red streak on each side from the base to the 4th segment. Anal tuft bluish black. Legs metallic blue, tarsi with a dingy white tinge. Forewing transparent, opalescent with blue margins and cross-veins, beneath pale orange at the base. Hindwing with narrow bluish black margins. 21—25 mm. Evidently very closely allied to the following *culiciformis* L. which is otherwise palaearctic. Nevada, British Columbia, Washington. The larva lives beneath the bark and in the wood of young alder-trees.

culiciformis. **S. culiciformis** L. (Vol. II, pl. 51 b). Head and thorax bluish black, palpi bluish black above, orange below, thorax below with a reddish orange spot on each side. Abdomen bluish black, the 4th segment red above

and beneath. Anal tuft bluish black. Legs bluish black, tibiae yellowish. posterior femora with a yellow band. Forewing transparent with bluish black margins and a bluish black cross-vein, strewn with reddish orange at the base, under surface faded golden yellow. Hindwing transparent with narrow bluish black margins. 21 to 28 mm. June. — Thus chiefly separated from *americana* by the forewing being golden yellow beneath and the yellowish brown hind tibiae. Kodiak, Alaska; Europe, North Asia. In Europe the larva lives in the wood of birch and alder trees, preferably in the stumps. The web is made between the wood and bark and surrounded with oblong splinters of wood.

S. caternaulti *Le Cerf*. Face blackish green, opalescent, white before the eyes. Palpi white below, blackish bronze above. Antennae purple black, very finely dentate. Collar blackish bronze. Thorax greenish black, margins reddish, spotted reddish beneath. Only the two first joints of the abdomen are preserved, they are black. Legs black and white. Forewing transparent, margins and veins purple black, the relatively narrow distal margin does not exhibit any yellow or reddish cells, but yellow is traceable beneath, the costa and inner margin are also dusted with yellow. Hindwing transparent, margins and veins black, fringes of all the wings blackish bronze. 24 mm. Guiana, Cayenne. Only 1 ♂ known. *caternaulti*.

S. tepperi *Hy. Edw.* (177 e). Head orange above, antennae black. Thorax orange above and beneath. Abdomen bluish black above, the 1st and 2nd segments and the anal tuft orange, abdomen beneath quite orange. Legs orange and blue. Forewing narrow, metallic blue with a narrow semi-transparent area and a strong cross-vein, beneath orange at the base. Hindwing transparent with bluish black margins, broadest at the apex. Under surface orange at the base. 23 mm. Georgia. Only 1 ♂ is known of this excellent species. *tepperi*.

S. texana *Hy. Edw.* (= *wittfeldii Hy. Edw.*) (177 f). Head brownish black. Palpi and collar orange. Antennae black, brownish below. Thorax black with a narrow orange streak on each side and a posterior transverse streak. Abdomen brownish black with orange rings on the 2nd, 4th, 6th and 7th segments. in the ♀ only on the 2nd, 4th and 6th, those on the 6th and 7th extending all round, the 5th segment orange beneath. Anal tuft brownish black, in the ♂ orange on each side below. Legs bluish black, spurs and hair-tuft orange. Forewing with a narrow hyaline area, the distal area scaled quite purple black, often strewn with orange, margins and cross-vein black. Costa and inner margin beneath orange. The ♀ is without any orange, but the forewing is almost entirely scaled purple black. Hindwing transparent with a very narrow bluish black or purple black margin above and beneath. 18—22 mm. Florida Texas. *texana*.

S. seminole *Beut.* (177 f). ♂: head and antennae brownish black. Palpi and collar in front light orange. Thorax brownish black with a narrow orange line on the patagia and a posterior broader termination. Abdomen metallic brownish black, the 2nd, 4th and two last segments behind narrowly orange. Anal tuft black, orange below in the middle. Middle and posterior femora blackish, tibiae violet with an orange band in the middle. Tarsi orange inside, violet outside. Forewing narrow, costal margin brownish black, distal margin orange, veins and margin dark, inner margin scaled orange, cross-vein distinctly orange. Hindwing transparent with some orange at the upper cell-end. ♀: similar to the ♂ in the marking of the abdomen and legs, but only the 2nd, 4th and last segments orange, the yellow on the forewing broader and stronger, especially the inner-marginal area which is bordered by the strong median vein. 15—18 mm. Lake Worth, Florida, February. *seminole*.

S. marica *Beut.* (= *marcia Dyar*) (177 f). Head black, palpi orange. Collar black, orange in front. Antennae and thorax black with distinct orange stripes laterally on the patagia, a broad orange transverse band on the posterior part, black below with an orange spot on each side. Abdomen brownish black with orange bands on the posterior edges of the 2nd, 4th, 6th and 7th segment. Middle and hind femora brownish black, tibiae and tarsi orange, the tibiae with a black ring near the end. Anterior coxae and femora inside brownish black, outside orange. Anal tuft black above, orange below. Forewing transparent, costal margin black, inner margin orange, fringe brown, cross-vein golden orange, distal margin broadly orange with black veins, an orange connection from the distal margin along the costal margin as far as the cross-vein. Hindwing transparent, costal margin narrowly orange, distal margin and fringe narrowly black. The ♀ has the forewings more broadly framed with orange, so that few hyaline places remain. 25 mm. Florida. *marica*.

S. praestans *Hy. Edw.* (177 f). Head black, with an orange tuft in front. Palpi bright orange. Thorax blackish bronze, striped orange on each side, spotted orange below. Femora blackish bronze, tibiae dark orange, the posterior ones of the deepest tint, tarsi more yellow. Abdomen blackish bronze, the 4th segment above copper-red, narrow copper-red bands on the last two segments. Anal tuft copper-coloured (red), the sides bronze. Forewing with broad blackish bronze margins and cross-vein, inner margin bright fiery red like almost the whole distal area so that only a round spot remains transparent, mostly traversed by three dark veins. Hindwing transparent, costal margin and part of the basal region bright orange, distal margins blackish bronze. Beneath all the scaled places are lighter orange than above. The ♀ has quite orange forewings except the black margins and crossvein; margins and veins of the hindwings likewise orange. 23 mm. Washington. *praestans*.

S. fragariae *Hy. Edw.* (= *orthocarpi Hy. Edw.*) (178 a). ♂: head black with a metallic blue reflection. palpi red, slightly black outside. Antennae bluish black. Collar red in front. Thorax metallic bronze, patagia

with red traces. Abdomen bronze-coloured, the 4th and the two last segments red above, the sides of the abdomen striped red. Anal tuft red, bluish black above on each side. Femora bronze-coloured, tibiae red, bronze at the ends, tarsi bronze, slightly red on one side. Forewing with broad margins and a broad cross-vein metallic green, so that few transparent places are left, inner margin broadly red from the base to the cross-vein, beneath the red is still more extensive. Hindwing transparent, red along the inner margin, distal margin brownish bronze. ♀: forewing quite metallic green or blue. Inner margin reddish orange, thus lighter than in the ♂, sometimes a narrow transparent streak in the cell and two or three between the veins in the distal area. Hindwing before the blackish brown fringe partly broad orange, cross-vein the same, so that only about half remains transparent. Anal tuft quite red. 15—22 mm. Nevada, Utah, Colorado. Unfortunately there is neither anything known of the life-history of this beautiful species. — var. **semipraestans** Cock. The orange colouring corresponds to *praestans* Hy. Edw., but the colour of the legs and the shape are of *fragariae*. The colour of the abdomen (blackish bronze, the 4th segment quite red, the last two segments narrowly red) resembles again more *praestans* than *fragariae* 24 mm. Florissant, Colorado, 2300 m; June. It flies very swiftly over dry sterile soil. COCKERELL is undecided whether *semipraestans* is a variation of *fragariae* or even perhaps a distinct species.

behrensi.

S. behrensi Hy. Edw. (= *elda* Hy. Edw., *helianthi* Hy. Edw.) (178 a). ♂: head black, face white with a violet reflection. Palpi and collar orange. Antennae black. Thorax metallic bluish or greenish black with a red stripe on the patagia and red spots beneath. Legs red, femora black, tarsi red and black. Abdomen metallic greenish or bluish black, the last 4 segments red, and red stripes along the sides of the first 3 segments, with red bands beneath. Anal tuft red, laterally bluish or greenish black. Forewing metallic bluish or greenish black with a red stripe at the inner margin, dull brownish black beneath; basal area, costal and inner margins red. Hindwing transparent, distal margin violettish brown, the inner margin and base red. ♀: head in front with a tuft of red hair. Abdomen: the 3 last segments above, all beneath and the anal tuft red. Hindwing quite scarlet, distal margin and fringe brown. 18—22 mm. This excellent species has so far only been found in California.

autremonti.

S. autremonti Le Cerf (176 f). ♂: face blackish blue. Palpi black, yellowish white outside on the 2nd joint. Antennae black. Collar and thorax blackish green, tegulae with traces of red, pectus beneath spotted red. Abdomen blackish green with miniate sides of the 2nd, 3rd and 4th segments, anal tuft red. Beneath blackish blue from the base to the 3rd segment, the 4th grey, the others whitish yellow. Anterior hips whitish yellow, spotted red outside, femora blackish blue, tibiae black, slightly mixed with yellow, middle and posterior hips yellowish white, middle and posterior femora blackish blue, tibiae of the same colour, terminated by whitish yellow hairs, spurs white, tarsi of all the legs blackish blue, curled white. Forewing greenish black, broadly whitish yellow beneath from the base to beyond the middle along the costa. Hindwing blackish bronze, a trilobate hyaline spot at the base, occupying almost half the wing. Fringes of all the wings greyish black. ♀: similar to ♂, but with an orange red abdomen beneath and a black anal tuft. Forewing beneath not yellowish white but orange as extensively as in the ♂. The hyaline part of the hindwing broader. 15 mm. Brazil, Minas Geraës; ♀ from Araraquara.

scythropa.

S. scythropa sp. n. (176 f) is very closely allied to *autremonti* Le Cerf, but it has all the parts black except the thoracal disc, the anterior pectoral sides and the two first palpal joints beneath, which are yellow. Wings like those of *autremonti*. 14 mm. Brazil, Itaitiaya. 1 ♀ leg. Prof. SEITZ; type: Senckenberg Museum.

tineosphracia.

S. tineosphracia sp. n. (180 h) is very closely allied to *S. autremonti*, *infusata* and *scythropa* which, together with a few more, would be best comprised under the genus *Trichocerata* Hmps.; *tineosphracia* might even be entitled to a separate genus, since the antennae of the ♂ are longer than usual (as long as the forewings) and exhibit a thickened area of appressed hair-scales in the centre above. Antennae, head, thorax and abdomen blackish brown, somewhat glossy, the antennae behind the thickening white for some distance, the tips again black. Legs lighter, the coxae silvery, abdomen beneath silvery white. Forewing rounded at the apex, densely scaled blackish brown. Hindwing: the costal region and a broad apical area semihyaline, scaled lighter greyish black, the rest purely hyaline, margins thin, fringe long, blackish brown. Under surface somewhat lighter. The ♀ evidently belonging to it has the same scheme and colouring on the wings, very long pointed palpi semi-circularly bent upward, the first two joints orange, the tips brown. Antennae blackish brown. Abdomen blackish brown, glossy, two parallel dorsal lines in a beautiful opalescent purple red, anal tuft brown. Abdomen beneath and anal tuft reddish orange. Middle legs blackish brown, coxae yellowish white, anterior and posterior legs absent. 14—15 mm. Brazil, Itaituba, types in the Berlin Zool. Museum.

dimorpha.

S. dimorpha Le Cerf (176 g). ♂: face black, white before the eyes. Palpi black, strewn with yellow scales. Antennae reddish yellow, black at the base and tips. Collar black, glossy. Thorax and abdomen blackish blue. Anal tuft blackish blue, laterally with a few yellow scales, ventral side black, segments 4—7 broadly margined with yellow, the last segment black at the base. Anterior hips blackish blue, partly covered with pale yellow scales, the femora and tibiae are likewise blackish blue, terminated by yellowish, middle tibiae partly.

whitish, the posterior ones with a white ring; tarsi of all the legs yellow, blackish beneath. Forewing transparent, margins, veins and discal mark black, beneath partly yellowish. Hindwing transparent, margins and veins black. Fringes of all the wings black. ♀: palpi whitish yellow, the 2nd joint with a black exterior line, the 3rd quite black. Anterior hips yellowish white, body and legs quite black. Forewing blackish bronze, hindwing broadly margined with black so that the greater basal part remains hyaline, divided by the relatively broad discal vein into a smaller area and towards the base into a larger area. 15 mm. Brazil, Caraca; the figured ♀ was taken by Dr. SEITZ at Rio Preto (São Paulo) on April 25th 1930.

S. infusata *Le Cerf* (176 f). Forewing above and beneath sooty black, the wedge-shaped area is merely *infusata*, a tiny hyaline spot near the discocellular vein, distal area just as small, traversed by two veins. Hindwing black with larger hyaline spots, a basal larger one divided by the median vein, one beyond the cell towards the apex and parted by vein 5 between veins 4 and 6. Head, antennae, thorax, abdomen and legs smoke-black. Palpi, anterior femora, margins of the 2nd and 4th segments dingy white. 1 ♀. 17 mm. Argentina, Andes of Tucuman; December.

S. flavostigma *sp. n.* (176 h). Head and antennae black. Thorax blackish brown with traces of a red- *flavostigma*, dish marking. Abdomen blackish brown. Forewing narrow, blackish brown, semihyaline at the base, at the cell-end a light ochreous spot on which the veins appear darker, distal area and margins blackish brown again. Hindwing transparent, thinly strewn with yellowish brown scales, margin black, rather broad at the apex, gradually diminishing outwards. Legs blackish brown, with reddish hair, especially at the ends of the joints. 25 mm. Rio de Janeiro. 1 ♂. Type: Coll. Hamburg Zool. Museum. Figured is a ♀ taken by Mr. W. MARTEN in Brazil.

S. mariona *Beut.* (178 a). ♂: head white, collar whitish grey, white beneath. Palpi white. Antennae *mariona*, blackish green. Thorax blackish green with a very broad red lateral line extending to the base of the wing. Abdomen and anal tuft metallic blackish green. Legs the same, anterior coxae white. Forewing metallic blackish green with a broad red inner-marginal line vanishing outwards, costal margin dingy white. Hindwing brown with a violet reflection, the central part with two hyaline areas, the upper one traversed by the cross-vein. 17—20 mm. Described according to 3 ♀♀; ♂ and early stages unknown. Trimble and Pagossa Springs, Durango, Colorado; July.

S. sanborni *Hy. Edw.* (178 b). Head dull brown. Palpi white, the 3rd joint black. Thorax and abdomen *sanborni*, dull bronze brown, the abdomen with narrow pale yellow bands above on the 2nd and 4th segments. Anal tuft pointed. Legs bronze brown. Forewing dull bronze brown, distal area with a white spot crossed by 3 or 4 dark veins. Hindwing transparent, margins and fringe violettish brown. 19 mm. Massachusetts. Only ♀♀ known.

S. ruficornis *Hy. Edw.* (= *minuta Hy. Edw.*) (178 b). Head and thorax violettish black. Palpi yellow. *ruficornis*, Collar yellow in front, patagia yellow behind. Antennae violettish black, reddish below. Abdomen violettish black with narrow yellow bands on the 2nd, 4th and last segments. Anal tuft broad, brush-like. Legs violettish black with yellow rings. Forewing violettish black with traces of red in the cell and in the distal area behind the cross-vein, very distinct in the ♀, beneath as above. Hindwing transparent, margin and veins violettish black. 10—14 mm. This very small species was hitherto only found in Georgia and Alabama (Southern States).

S. subaerea *Hy. Edw.* (178 b). Head and thorax deep brown, thorax behind with a yellow marking. *subaerea*, Antennae with a pale yellow band before the end. Palpi yellowish. Abdomen brown strewn with yellow scales, and with traces of bands on the 4th, 5th, 6th and 7th segments. Anal tuft brown and yellow. Forewing purple brown strewn with yellow scales. Hindwing purple brown, hyaline at the base; all the wings beneath strewn with yellow. 14 mm. Apparently only 1 ♂ known. Arizona.

S. nigra *Beut.* (178 b). Head black, face dingy white. Palpi white, blackish outside. Collar in front *nigra*, dingy white. Antennae and thorax black, patagia feebly marked white. Abdomen black with posterior whitish margins on the 2nd, 4th and last segments, the 4th being broadest and extending around the abdomen. Anal tuft black. Legs black, anterior coxae marked with white, posterior tibiae with a white band. Forewing black with a light streak in the cell and a few whitish streaks between the veins of the distal area; beneath yellow along the costa. Hindwing black, slightly hyaline at the base. 14 mm. Colorado, Utah. Only ♀♀ are known.

S. verecunda *Hy. Edw.* (178 b). Head black with dingy yellowish hair. Collar white. Antennae black, *verecunda*, yellowish below. Palpi white. Thorax black with a dingy yellow line on the sides, and with a white spot beneath on each side. Abdomen black with dingy white bands on the 4th and last segments. Legs black, femora with little white. Forewing brownish black; lighter, almost whitish, at the inner margin, in the cell and between the veins of the distal margin. Hindwing quite brown, somewhat lighter at the upper basal part. 19 mm. Colorado. The ♂ is still unknown.

S. polygoni *Hy. Edw.* (= *meadii Hy. Edw.*) (178 b, c). ♂: head and collar black. Palpi scarlet, black *polygoni*, outside. Thorax black with a blue reflection, patagia behind feebly-reddish, beneath with a red spot on each

side. Legs black, middle and hind tibiae with a broad scarlet band. Abdomen bluish black, opalescent, the 4th and the two last segments scarlet, the others laterally scarlet. Anal tuft scarlet with bluish black sides. Forewing metallic bluish black with a scarlet stripe at the inner margin, which extends somewhat beyond the middle, fringe brown, reddish beneath at the base. Hindwing transparent, margin violet, base and the beginning of the inner margin red, fringe brown. ♀: similar to the ♂, but the hindwing is quite scarlet, lighter, with a very broad brownish black distal margin, with a violet reflection. The 4th and last segments of the abdomen scarlet, lateral line the same. 18—20 mm. Only known from California. Larva in the root of species of *Polygonum*; it emerges shortly above the soil.

achillae. **S. achillae** Hy. Edw. (= *cremocarpi* Hy. Edw.) (178 c). Head, collar and antennae black. Palpi black, red beneath at the base. Thorax metallic bluish black with little red patagia and a red spot on each side beneath. Abdomen above and beneath quite metallic bluish black. Anal tuft red, bluish black above on the sides. Legs completely bluish black. Forewing metallic bluish black or greenish black with a red streak on the inner margin, extending from the base to about the middle of the wing. Hindwing transparent with bluish black margins. 15—18 mm. California. 2 ♂♂.

floridensis. **S. floridensis** Grt. (178 c). Head and antennae black. Palpi black at the base, reddish apically. Collar red. Thorax bluish black with a very prominent red transverse marking on the hindmost part, and a red spot on each side beneath. Abdomen bluish black, the 4th segment above and beneath bright red, narrow red belts on the two last segments above. Anal tuft black, feebly white laterally. Legs black, tarsi red, hind tibiae red with a black band, anterior coxae with a red stripe. Forewing metallic purple black with a transparent basal streak, cell and inner margin bright red, beneath almost quite red, veins dark. Hindwing transparent with violettish brown margins, the margins beneath red, fringe brown. 14—18 mm. Florida. Apparently only ♂♂ are known.

geliformis. **S. geliformis** Wkr. (178 c). Head, thorax, palpi, antennae and legs quite black with a greenish reflection. Abdomen above and beneath bright red except the 1st segment which is bluish black. Anal tuft red, laterally black. Forewing above and beneath quite bluish black. Hindwing transparent, the margins broader brownish black than usual. ♂ 10 mm. ♀ 15—19 mm. Florida, St. Vincent (British West Indies), Mexico.

sapygaeformis. **S. sapygaeformis** Wkr. (178 c). Head and antennae black. Palpi red, black outside, especially at the base. Collar red. Thorax black with a red posterior transverse marking, a red spot beneath on each side. The first 3 segments of the abdomen black, in the ♂ the last four, in the ♀ the last three above and beneath red. Anal tuft black. Legs red and black, tibiae with a broad red band. Forewing bluish black, purple outside with a red streak which is transparent at the base; beneath red from the base almost to the middle, dark outside. Hindwing transparent, distal margin violettish black, rather broadly scaled at the apex. 17—19 mm. Florida.

animosa. **S. animosa** Hy. Edw. (178 c). ♂: head and antennae bluish black, palpi red, tips black, sometimes mixed with black hairs. Thorax blackish bronze, patagia red behind, a red spot on each side beneath. Abdomen blackish bronze, the last segment red, the three preceding ones laterally red. Anal tuft red, laterally black. Legs greenish black. Forewing metallic greenish black with a red inner-marginal streak extending to beyond the middle. Beneath as above. Hindwing transparent, the narrow margins brownish black. ♀: head, thorax, legs and forewings as in the ♂, fully scaled, but the hindwings likewise metallic greenish black or bluish black, above and beneath. The last three adominal segments laterally red, all are black above. Anal tuft also black. 16—20 mm. Arizona.

pyralidiformis. **S. pyralidiformis** Wkr. (= *nigella* Hulst) (178 d). Head purple brown. Palpi and collar yellow. Thorax purple black with very narrow light stripes on each side and yellow spots beneath. Abdomen purple black, the 4th segment quite yellow above, the posterior margin of the last segment with a yellow belt, absent in the ♀. Anal tuft purple brown, feebly yellow on the sides. Legs purple brown, hind tibiae with yellow rings before the end, tarsi light. Forewing purple brown, densely scaled, yellow beneath at the base. Hindwing transparent with a narrow purple brown margin. 14—20 mm. From Canada to Texas.

ruficaudis. **S. ruficaudis** Wkr. Metallic blue with a coppery or purple lustre. Orbita silvery, head yellow behind. Palpi erect, golden yellow. Antennae black. Abdomen tapering off behind, more than thrice as long as the thorax, bright red towards the end, which colour passes over into the long anal tuft exhibiting here also a few black hairs; beneath golden yellow. Legs slender, golden yellow, posterior femora purple, very short, hind tibiae purple at the end, hind tarsi long and purple. Forewing transparent, very narrow, costa, distal area and cross-vein purple. Hindwing transparent, all the fringes purple. 22 mm. Ega.

rhysaeformis. **S. rhysaeformis** Wkr. ♀: bluish green. Head coppery, white in front on each side, and with white hair behind. Palpi whitish, black apically. Antennae very much longer than the thorax, rather thick at the ends. Thorax with a yellow streak on each side. Abdomen with white bands on the posterior margins of the segments; beneath white, anal tuft with a few scale-hairs on each side. Legs with white bands. Wings transparent: forewing with a purple brown costa, distal area and discal band. 18 mm. The doubtful ♂ of it is

said to be bluish black, palpi above black. Antennae filiform, plain, rough below. Anal tuft with fewer pale hairs than in the ♀. Forewing with a broader scaled part in the distal area. Para.

S. blaciformis Wkr. Green. Face white. Collar with white hair. Palpi white below. Antennae club-shaped, hairy beneath, twice as long as thorax. Pectus white. Abdomen almost thrice as long as thorax. Anal tuft black, very long. Legs with white bands. Forewing transparent, cross-vein and margins purple. Hindwing the same. 18—20 mm. Amazon Valley. 1 ♀.

S. pulchripennis Wkr. Dark blue, of a slender structure. Head silvery white in front and at the posterior edge. Palpi oblong, silvery white. Antennae black. Abdomen almost three times longer than the thorax. Anal tuft very long. Anterior coxae silvery. Anterior tibiae very short, silvery beneath, hind tibiae with a silvery band and silvery hair-tufts, anterior tarsi silvery beneath, posterior tarsi densely white-haired and with a white hair-tuft at the beginning. Forewing blue, transparent at the base, distal area mostly purple. Hindwing transparent, veins, margins and fringe black. 22 mm. Ega. 1 ♂.

S. edwardsii Beut. (178 d). Head black. Face and palpi white with a black exterior streak. Antennae and thorax black with a very narrow line on each side. Abdomen black with dingy yellow bands on the 2nd, 4th and last segments. The 4th segment yellow above and beneath, the 5th only beneath. Anal tuft black, yellowish on the sides. Femora black, middle and hind tibiae yellow with a black ring at the end. Tarsi yellow and black, anterior coxae white. Forewing dull brownish black, warming into violet with a few yellow streaks in the cell and behind the cross-vein, the yellow more intense beneath. Hindwing dingy dark yellow, veins and margins violet, a quite transparent light brown stripe between veins 1 a and 2. 24 mm. Colorado. The ♂ is not yet known.

S. florisantella Cock. is very similar to *S. arctica* Beut. (177 b). Antennae black, basal halves below finely dentate. Hindhead with long rough pale hair, cheeks and face whitish. Palpi long and bristle-like, black outside, white above and inside. Proboscis small. Thorax black above, with a metallic green reflection, the sides with black and white scales, a distinct white spot below near the base of the wings, collar coppery. Legs black and white, the long hair of the femora beneath white, spurs whitish. Forewing purple black with scattered white scales, a small white spot in the cell and distinct white streaks in the distal area between the dark veins. Hindwing transparent pearly white, costa and veins black, fringes of both wings long and black. Abdomen purple black, a trace of white on the 2nd, a narrow purely white band on the 4th and penultimate segments. Anal tuft black. 14 mm. Florissant, Colorado. 1 ♂ in June, at a dry place. COCKERELL somewhat doubtfully refers to the hitherto unknown ♂ of *S. nigra* Beut. (178 b).

S. utahensis Beut. Head black. Face and palpi golden yellow. Collar yellow in front, the rest black. Antennae black with a blue reflection. Thorax brown with a broad yellow band along the patagia and a yellow shoulder-spot at the base of the forewing. Posterior margin of the thorax with yellowish hair. Femora golden yellow above, brown beneath, tibiae golden yellow with a broad brown band at the tips, the first tarsal joint golden yellow, the following ones brown. Abdomen with a very broad golden yellow band on the posterior part of the 2nd segment above and beneath, the 4th and last segments quite golden yellow; the 1st, 3rd and 5th above brown with few yellow scales, brown beneath, except the 5th which is quite golden yellow. Anal tuft golden yellow, black in the middle and laterally. Forewing brown with the otherwise hyaline spots golden yellow, similar to *edwardsii* (178 d) to which it is allied. Hindwing golden yellow at the base, outside as well as the fringe brown. 23 mm. Washington County, Utah. In June. Only 1 ♀.

S. pyrosoma Meyr. Head reddish, mixed with orange. Palpi orange, whitish at the base. Antennae dark brown. Abdomen reddish orange. Anal tuft from dark blue to reddish. Forewing dark blue with a reddish reflection, a reddish orange basal spot, a subtriangular hyaline spot at the end of the cell, discal vein strong, distal area hyaline, crossed by four dark brown veins. Fringe dark rust-coloured. Hindwing hyaline, veins blackish, a narrow thickened black spot on the cross-vein between 5 and 7, a dark brown irregular distal margin, broadest at the costa, enclosing a blurred yellowish apical spot; margin reddish orange. Fringe brownish. 13 mm. British Guiana, in April. Only 1 ♀.

S. halmyris Drc. Forewing black, the end of the cell and a round spot below it hyaline. Hindwing transparent, fringe black. Head, thorax and abdomen black, base of abdomen slightly yellowish. Antennae black with a broad white preapical ring. Legs greyish black. 25 mm. Mexico: Rincon. Guerrero, 950 m. September.

S. hispides Drc. Forewing dark black, the cell and a round spot at the end of it semitransparent. Hindwing hyaline, veins and fringe black. Head, thorax and abdomen lustrous black, thorax beneath white. Antennae and legs black. 19—20 mm. Mexico: Amula, Guerrero, 2000 m; August.

S. ventralis Drc. Head, antennae, palpi, tegulae, thorax, abdomen, and legs black. Collar and anal tuft bright red, below with a few long black hairs. All the wings hyaline, costal and distal margins of both wings black, veins the same. 25 mm. Eastern Peru! Chanchamayo, 2000 m. 1 ♂.

- ceraca*. **S. ceraca** Drc. Forewing dark purple brown, a streak from the base to the end of the cell hyaline, the space beyond the cell broadly golden yellow, fringe dark brown. Hindwing hyaline, veins, distal margin and fringe dark brown, almost black. Head and palpi black, face white, collar steel-blue. Thorax dark brown. Abdomen orange, the two anal segments and anal tuft blackish brown. Legs bluish black. 37 mm. British Guiana: Essequibo River.
- rufa*. **S. rufa** Btlr. Wings above orange with black margins, fringe grey; the margins of the forewing very broad, showing the ground-colour only at the cell-end, parted besides by a black streak. Body black with a bluish grey lustre. Abdomen with white posterior margins on all the segments. Antennae black, wings bronze beneath, body lead-coloured beneath, pectus laterally steel blue. Legs purple above, bronze below, middle tibiae above covered with orange hair. 10—17 mm. Near Valparaiso on Umbelliferae in January.
- cubana*. **S. cubana** H.-Schöff. Antennae, forewing, fringe of hindwing yolk-coloured. Segments 5—7 of abdomen bright cinnamon red, segments 1 and 2, the posterior margins of 3 and 4, and the end of the posterior tibiae black. Abdomen pointed, the anal tuft is said to be absent. Similar to *uroceriformis* (Vol. II, pl. 51 f). Cuba.
- tabogana*. **S. tabogana** Drc. (176 g). Forewing dark brown, inner margin yellowish hyaline. Hindwing yellowish hyaline, margins and fringe brownish black. Head, thorax and abdomen black, posterior part of the thorax and of the abdomen with yellow bands. Antennae black, palpi and collar pale yellow. Legs above black, beneath yellowish white. 20 mm. Panama, Taboga I.
- semitrista*. **S. semitrista** sp. n. (176 i). ♂: at first sight very similar to *S. basalis* Wkr., particularly by the long divided anal tuft. Antennae, head, thorax and abdomen black, palpi brownish, white beneath. Thorax above with two slightly orange longitudinal stripes, reddish orange beneath, ventrum and anal tuft in the middle silvery white. Legs black, posterior tibiae in the middle whitish, tarsi black and white. Forewing transparent, veins, the strong costal margin and the discal vein black. Distal margin not very broad. Hindwing transparent, veins and the very narrow margin black. 22 mm. The ♀ belonging to it is quite different. Antennae, head, thorax and abdomen as well as the small pointed anal tuft lustrous black. Palpi black. The 2nd joint slightly haired whitish. Forewing black, gradually warming into an intense light yellow behind the discal vein towards the distal margin. Hindwing transparent, a dark shadow at the costal margin as far as the centre of the wing and between veins 2 and 3. Fringes of all the wings black. Legs black, hind tibiae brownish inwardly. 28 mm. Rio de Janeiro. 1 ♀. Types: Coll. MARTEN. As the couple was found in copula by Mr. MARTEN in Rio, there can be no doubt whatever about their belonging together. The group of the *Aegeriidae* becoming better known, dimorphism is also getting more frequently evident. February, April, Rio de Janeiro, type in Coll. MARTEN.
- aerosa*. **S. aerosa** sp. n. (178 d). Antennae, head, thorax and abdomen blackish blue, with a metallic bluish reflection. Palpi yellow, lighter inside, the two last joints outside blackish brown, silvery white before the eyes. Thorax with two coppery orange lateral stripes. The 2nd abdominal segment with a broad coppery orange band, the others only with coppery orange posterior belts. Anal tuft blackish blue with a violet shine. Ventrum coppery orange. A ♂ shows the belts of the abdominal segments less developed and of a more yellowish tinge, a lighter ventrum, the anal tuft beneath again beautifully orange. Legs orange, hind tibiae black before the end. Forewing transparent, the stronger costal margin, the distal margin of medium width, discal vein and veins black. Hindwing transparent, veins and margins black, the last part of the discal vein colourless. 16 to 17 mm. Brazil, Itatiaya. December. Types: Coll. MARTEN.
- apicalis*. **S. apicalis** Wkr. ♀: metallic green with purple and coppery scales. Proboscis moderately long. Palpi erect, all white in front, 3rd joint pointed, of one third of the length of the 2nd. Antennae gradually thickening. The scaled legs are rather long, tarsi beneath dingy white. Forewing purple black, dusted whitish and with white veins in the distal area. Hindwing with two black purple stripes proceeding from the base, a costal one, the other one at the inner margin. Fringes of all the wings purple. 28—30 mm. Nanta.
- ceres*. **S. ceres** Drc. Forewing black, greenish at the base, a small round spot below the cell near the anal angle and the hindwing hyaline, margins and fringes black. Head, palpi, thorax and abdomen black. Anal tuft black. Legs black, with yellow bands. 20 mm. Guatemala, Totonicapan, 3000 m.
- modesta*. **S. modesta** Btlr. All the wings hyaline, veins, distal margin and fringe blackish brown. Forewing with a rosy tinge, a dark green costal margin, a copper-brown inner margin, discoidal cell brown. Head blackish green, antennae above black, rusty brown below. Palpi scaled, with a black median line above. Eyes inwardly silvery white. Thorax purple blue above, steel-blue beneath strewn with gold-coloured scales. Femora of legs steel-green, tibiae of the first pair black outside, golden inside, of the second pair dark green with three golden spurs, of the hind pair above dark blue, with straw-coloured and purple bands with two golden middle and terminal spurs, tarsi black above, golden below. Abdomen above simply smooth, steel-blue, scaled beneath. Anal tuft golden. Wings beneath coppery golden at the margins. 17 mm. Espiritu Santo.
- hades*. **S. hades** Drc. All the wings unicoloured, lustrous bluish black, veins and distal margins dull black, beneath the same. Head, thorax and abdomen bluish black. Head beneath and prothorax white. 19—20 mm. Mexico: Teapa, Tabasco; in February.

S. proserpina *Drc.* Forewing lustrous blackish green. Hindwing dull black, at the base about one *proserpina*. third hyaline. Head, palpi and antennae black. Collar and thorax beneath reddish brown, thorax above and legs black. Abdomen absent. 19 mm. Guatemala, San Geronimo.

S. theobromae *Busck*, from the Isle of Trinidad, described in Bull. dept. agric. Trinidad 9 (1910) 1911. *theobromae*. The literature dealing with it was not obtainable.

S. gehleni *Coll. Closs*, Int. Ent. Zeitschr. 16, p. 118, ♂ (1922) is no *Aegeriida*, but a *Sphingida*. Bolivia. Wrongly *gehleni*, ranged in Lep. Catal. Junk. Vol. 31: *Aegeriidae*.

S. omphale *Say*. Amer. Ent. 2, p. 42, p. 19 fig. 5 (1825) is not an *Aegeriida*, but a *Syntomida*, which mistake is to *omphale*. be pardoned considering the state of entomology at that time. Wrongly ranged in Lep. Catal. Junk. Vol. 31: *Aegeriidae*.

5. Genus: **Dipsosphecia** *Spul.*

Proboscis stunted, otherwise very similar to *Synanthedon*; veins 11 and 12 of forewing towards the costal margin. Type: *D. ichneumoniformis* *F.* from Europe.

D. m llinipennis *Bsd.* (= *resplendens* *Hy. Edw.*, *artemisiae* *Hy. Edw.*, *senecioides* *Hy. Edw.*) (178 d). *mellinipennis*. ♂: head black, palpi golden yellow, collar in front golden yellow, antennae jet-black, slightly reddish below, thorax jet-black with a golden line on each side and a golden transverse band behind. Thorax beneath golden yellow. Abdomen black, the 2nd and the last 4 segments with a broad golden band. Anal tuft black, yellow beneath. Golden yellow legs with black bands on the tibiae. Forewing transparent, margins, cross-vein and veins brownish black with more or less copper red between the veins, especially somewhat behind the cross-vein outwardly. The wedge-shaped area and a spot behind the cross-vein remain transparent. Hindwings transparent with brown narrow distal margins, before them as well as the costa narrowly copper-red. ♀: similar to the ♂, the forewing mostly still more extensively red which sometimes warms into yellow. The last 3 segments broadly yellow. Anal tuft yellow, with a black spot in the middle. 22—27 mm. Sierra Nevada, California, Durango, Colorado. Regarding the early stages of the beautiful, rather variable insect, the larva is reported to live in the wood of *Ceanothus thyrsiflorus*. The pupa is to be found in the bark.

D. deipyla *Drc.* (176 h). Forewing golden yellow hyaline, costal margin and apex brown, apex striated *deipyla*. yellow, discal band brown, outwardly yellowish, inner margin yellow. Hindwing hyaline, veins and fringe black. Head and thorax black, patagia and posterior margin yellow, palpi yellow. Antennae black above, red-brown below excepting the tips. Abdomen black, all the segments margined with lemon-colour. Anal tuft black mixed with white. Beneath the abdomen is quite yellow. Legs pale yellow. 19 mm. Panama, Bugaba, at an altitude of 300—500 m.

D. telecta *Le Cerf* (176 h). Head black, with yellow hair behind. Face bronze-black, white before the *telecta*. eyes. Palpi reddish yellow, outside with a broad black line on the 2nd and 3rd joints. Antennae thick, black, yellowish outside. Collar bronze-coloured, oscillating. Thorax black, covered with fine grey hair, patagia broadly yellow, posterior margin with yellow hair, slightly spotted yellow beneath. Abdomen black, all the segments except the 1st margined with a bright yellow. Anal tuft black, mixed with yellow in the middle and laterally. Ventrums black, the margins of the 4th to 7th segments almost quite yellow. Legs bluish black with much yellow. Forewing with a yellow spot at the shoulder, margins and veins blackish brown, distal margin pale reddish like the anal margin, the discal vein exhibits an intense red shadow outwards, the hyaline areas are well developed. Hindwing transparent. Veins and margins blackish blue, the discal vein feebly reddish. 23 mm. Brazil, Caraca.

6. Genus: **Podosesia** *Mschlr.*

Palpi erect, extending to the height of the head, with long loose hair on the 1st and 2nd joints, the 3rd long and bare. Antennae gradually thickened towards the ends, but terminating pointedly, with ciliary tufts in the ♂, plainer and shorter in the ♀. Abdomen compressed at the base, anal tuft plain in both sexes. Hindlegs very long and set with short hairs. Forewing with 12 veins, 7 and 8 stalked. Hindwing with stalked veins 4 and 5, 7 and 8 very long, vein 1 a present, discocellular vein oblique. Type: *P. syringae* *Harris*.

P. syringae *Harris* (= *longipes* *Mschlr.*, *denudatum* *Osborne*) (176 g). Head black, palpi chestnut brown, *syringae*. black beneath. Collar chestnut brown. Antennae reddish, blackish above. Thorax deep brown, reddish at the margins. Abdomen black intermixed with reddish, sometimes with a small yellow spot, or even a yellow band, on each side of the 4th segment. Femora black, anterior pair of tibiae orange, tarsi yellow; middle and hind tibiae black with an orange band, tarsi yellow, the posterior pair above with a black margin. Forewing deep brown with a violet reflection, generally with a rusty red streak below the costa outwards. At the base there is a short transparent streak, edged with red at the costa and inner margin. Beneath faded yellow and orange. Hindwing yellowish transparent, with a blue reflection. veins and margins deep brown, sometimes warming into reddish. 25—36 mm. New England and Central States, to the west as far as Colorado, and to the south as far as Texas. — The ♀ deposits her eggs on rough or nodular places in the bark of ashes and Spanish lilac. The larvae, soon after emerging, penetrate into the sound wood, where they build long canals of 20—25 cm.

The pupation also takes place in these passages near the bark, of which a very thin cuticle remains. After a three weeks pupal stage the imago emerges in June, July.

fraxini. **P. fraxini** *Lugger* (177 g). Head black, face dingy whitish. Palpi dull orange mixed with black hairs. Collar red in front, yellow behind. Antennae reddish. Thorax blackish, edged with yellow laterally and behind. Abdomen black with posterior yellow segmental margins, the 4 last segments may occasionally be quite yellow, darker orange on the sides. Forewing yellowish brown, transparent at the base, where it is now and then spotted red, golden yellow beneath. Hindwing transparent, margin and veins yellowish brown, yellowish beneath. 25—35 mm. Montana, Dakota, Minnesota. Larvae in ashes or lilac, like the *syringae*.

comes. **P. comes** *Heinr.* Antennae above black, nut-brown inside, rather densely scaled yellow outwards, basal joint whitish yellow. Palpi black, yellowish white above. Head black, collar yellow above, white and black laterally. Thorax black, yellow laterally below, patagia feebly yellow, a yellow triangular spot on each side of the metathorax. Forewing transparent, costa black with little orange, discoidal vein orange, the veins black with little orange, distal area orange, striped black along the veins, fringe black. Hindwing transparent, veins black, costa orange, especially beneath, fringe black. Abdomen black, the segments 2, 3, 5, 6 and 7 with a narrow yellow band, of which only the fourth extends also beneath. Anal tuft black and yellow. Legs bluish black, anterior coxae laterally yellow, the insides of the tibiae and tarsi with white and yellow scales, the spurs of the hind tibiae white. The ♀ has only 4 yellow abdominal bands, the anal tuft above quite yellow, laterally black. 16—19 mm. Brush Corral, Arizona. Larva in wood-galls on white oak.

7. Genus: **Gaea** *Beut.*

Palpi rather short, stretched, scarcely rising, thickly covered with short hair, the last third bare. Male antennae not very long pectinated, female antennae not pectinated. Hind tibiae above with short hair. Forewing with 11 veins, 7 and 8 stalked. Hindwing little rounded, almost triangular, cross-vein very oblique, vein 2 from the cell, 4 and 5 from the angle of the cell. Tongue stunted. Abdomen cylindrical with a smooth straight anal tuft. Type: *G. solituda* *Hy. Edw.*

emphytiformis. **G. emphytiformis** *Wkr.* (176 g). ♂: head in front whitish. Palpi and collar orange. Thorax purple brown with a yellow shoulder-spot, abdomen blackish brown with a yellow ring on each segment. Anal tuft black with few yellow hairs. Legs red with yellow traces, femora black, tibiae with black stripes. Wings purple copper-coloured. Forewing yellow, partly red in the disc, interrupted by the discal spot. Hindwing slightly mixed with red, transparent near the base. ♀: head in front dingy white, palpi and collar orange. Antennae dull orange with blackish tips. Abdomen behind with yellow bands on the 2nd, 4th and 6th segments and traces on the 5th segment; the 4th extends down to the under surface, anal tuft orange, black beneath and laterally. Legs orange, femora blackish. Forewing purple brown with a red spot in the cell and a few streaks of the same colour above the discal spot between the veins, some red being also at the base of the inner margin. Hindwing purple brown, transparent from the base to the middle, red at the inner margin, especially towards the base and at the costa. Under surface dusted reddish. ♂ 21 mm, ♀ 18 mm. United States; habitat not mentioned.

solituda. **G. solituda** *Hy. Edw.* (176 g). Head and thorax brownish, with yellow lateral stripes. Collar, face and palpi dull yellow. Antennae dingy brown, orange in the middle. Forelegs and middle legs yellow and orange. Hindlegs orange with a broad yellow margin at the tibiae. Abdomen brownish with 6 broad pale yellow orange bands, the 4th extending around the abdomen. Anal tuft black, yellow in the middle. Forewing dark brown with a red and yellow shadow from the base along the inner margin, another shadow above it to the cell, the discal mark remains dark, the distal area is lighter again, though the veins remain dark here. Hindwing transparent at the base, the distal parts of the wing are yellow and orange with dark veins, all the fringes brown. All the wings beneath brighter yellow and orange with dark veins. ♂ 28 mm, ♀ 32 mm. Texas and Kansas.

arizonensis. **G. arizonensis** *Beut.* Forewing yellowish orange red, brownish between the veins, all the veins dark brown, discal mark dark brown, edged with reddish orange. Hindwing transparent, veins brown, distal margin reddish orange, fringe brown; forewing beneath with still more extensive orange. Head black, palpi yellow. Antennae reddish orange, brownish towards the ends. Abdomen brownish black with a broad yellow band on the posterior margin of each segment, except the 4th, the posterior 3 bands broader than the anterior ones. Anal tuft lemon-coloured. All the segments beneath with yellow bands. Forelegs yellow, joints and femora black, the other legs are absent. 25 mm. Only 1 ♀. Pinal Mts., Arizona.

palmi. **G. palmi** *B. & McD.* (♀ = [*Synanthedon*] *palmii* *Beut.*). ♂: antennae strongly serrated. Palpi rather long and pointed, white beneath, the 3rd joint reddish. Head white mixed with ochreous. Thorax black with a pale ochreous central stripe and two lateral stripes. Abdomen greyish ochreous, anal tuft black, laterally ochreous. Legs dingy ochreous, coxae blackish. Forewing smoke-coloured with an orange shade, a thick black discal spot follows upon an orange spot which may also occur splash-like beyond the discal spot, fringe dark, hindwing orange at the base, broadly dusted smoky outside, a narrow discal spot and the fringe dark.

Forewing beneath with more prominent orange colour. ♀: head and palpi dark brown. Collar slightly mixed with white. Antennae brownish black with a blue reflection. Thorax bluish black with a broad white stripe on each side. Abdomen dark brown with a blue reflection and a broad white band at the posterior margin of the 2nd segment. Anal tuft dark brown with a white stripe on each side. Body beneath quite brown like the legs. Anal tuft beneath with two short white stripes not extending to the end. Forewing brown with a purple reflection and a small white spot at the cell-end. Hindwing quite brown. Beneath as above, forewing whitish along the costa. 28—30 mm. At the beginning of October. Arizona. Larva in a composite: "burrobush". — Thus a particularly strong sexual dimorphism prevails in this species.

8. Genus: **Euhagena** Hy. Edw.

Palpi slightly erected, the 1st and 2nd joints below covered with long hair, the 3rd joint long and hairless. Head, thorax, femora and tibia with long hairs. Antennae uniformly thick with very long combs in the ♂, plainer in the ♀. Tongue absent. Abdomen with appressed hair. Anal tuft like a flat fan in the ♂, small and inconspicuous in the ♀. Forewing with 12 veins, 7 and 8 stalked. Hindwing with vein 2 from the cell, 4 and 5 from the angle of the cell, veins 7 and 8 faded, discocellular very oblique. Type: *E. nebraskae* Hy. Edw.

E. nebraskae Hy. Edw. (= *coloradensis* Beut.) (176 h). Head black, face and palpi white, palpi below with long black hair. Thorax velvety black with traces of whitish hairs. Abdomen deep black with silvery white rings at the posterior margins of the 2nd, 4th, 6th and 7th segments, not extending around the abdomen. Anal tuft black. Legs black, tarsi marked white. Forewing deep orange changing to cold bluish, costal and distal margins black. Discal mark oblique, black. Hindwing of the same colouring interspersed with black. Fringes of all the wings brown. ♂ and ♀: 17—26 mm. Nebraska and Colorado; October. This peculiar *Sesia* is easily noticed by its extreme colouring. *nebraskae*.

9. Genus: **Chamanthedon** Le Cerf.

Smaller lepidoptera of a slender shape. Head small, the 3rd palpal joint short and pointed. Proboscis entirely stunted. Body slender, long, laterally slightly compressed, anal tuft normal. Wings long and narrow. Forewing: 1 a rudimentary, not forked at the base, 2 arises at the interior angle of the cell, 3 from it, 7 and 8 stalked on $\frac{1}{3}$ of their length, 9 from the anterior angle of the cell, 10 absent, 11 withdraws from 9 at the base. Hindwing: 1 a obsolete, 2 before the cell-angle, 3 and 4 from the latter, stalked on $\frac{1}{5}$ of their length, 5 from the cell, 6 from the anterior angle, 7 absent. Type: *Ch. hypochroma* Le Cerf (Vol. X, pl. 94 b) from Burma.

C. gaudens Rothsch. (177 g). ♂: Legs purple brown. Palpi and a spot below the eyes scarlet. Antennae black, head and thorax purple, collar and the broad margin of the thorax scarlet. Abdomen brownish black, basal segment scarlet, anal tuft reddish brown. Forewing bright purple, a scarlet band beyond the cell, followed by a transparent one, $\frac{1}{5}$ as far as the distal margin scarlet orange, fringe brown. Hindwing from the base about $\frac{3}{5}$ transparent, the rest as far as the margin purple brown. 22 mm. Rio Grande do Sul, Brazil. *gaudens*.

C. aurantiibasis Rothsch. (177 g). Legs and palpi orange. Head black, antennae brown. Thorax blackish brown with two blue spots, the sides brick-red. Abdomen brick-red, anal tuft wood-brown. Forewing: basal third brick-red, median semitransparent, a broad brown band at the cell-end with a brick-red centre, the area towards the distal margin pale wood-brown. Hindwing transparent with a reddish brown margin. 18 mm. Marcapata. Eastern Peru, 1200 m. *aurantiibasis*.

10. Genus: **Pyropteron** Newm.

In 1835, NEWMAN described this genus for *chrysidiformis* Esp. from Europe, apparently considering the peculiar red colouring more than morphological characters; the latter are so insignificant that they are difficult to distinguish from the following genus *Chamaesphecia*. The authors to-day generally comprise *chrysidiformis* and its allies with the other species of the genus *Chamaesphecia*; we bring the genus only because we follow the classification in JUNK's Catalogue, where also the subsequent species is enumerated.

P. chrysomelaena Le Cerf (176 h). Head blackish purple, face glossy white. Palpi golden yellow, the 3rd joint rather long. Antennae above black, reddish beneath, yellow at the base. Collar golden yellow, thorax purple black, metathorax above, pectoral sides below with two golden yellow spots. Abdomen black, the 1st segment quite golden yellow, the 2nd laterally, and the posterior margins of the 5th, 6th and 7th segments also golden yellow. Anal tuft trilobate, black, laterally golden yellow. Ventrums black, the first segment golden yellow. Legs predominantly bright golden yellow, the ends of the tibiae black. Forewing transparent, margins, veins, discal vein black, distal area rather broad, the distal hyaline area almost quadrangular, crossed by five veins; this area is dusted yellow beneath. Hindwing transparent, veins and margins black, base and anal margin golden yellow. Fringes of all the wings purple black. 17 mm. Brazil, Rio de Janeiro. 1 ♂. *chrysomelaena*.

11. Genus: **Chamaesphecia** *Spul.*

Chiefly separated from *Synanthedon* by the neurulation of the wings. Veins 10 and 11 of forewing are confluent towards the margin and generally fused already in the last third, vein 1 is only preserved in the basal part, the remainder being only indicated by an elevation of the wing-membrane. The interior branch of the inner-marginal vein disappears very soon; veins 3 and 4 arise on a common short stalk. Most of the species have a strongly developed tongue.

minima. **Ch. minima** *Le Cerf* (176 h) is one of the smallest *Aegeriidae* hitherto known. Head blackish blue, laterally whitish, face and palpi white. Antennae black, white before the tips. Collar, thorax and abdomen blackish blue. Anal tuft somewhat darker, ventrum brownish bronze, the last segment laterally white. Legs white marked with brownish bronze. Forewing transparent, margins and veins brownish bronze, the costa beneath whitish. Hindwing transparent, veins and margins as well as the fringes of all the wings brownish bronze. 9.5 mm. Bogota; February. 1 ♂.

pluto. **Ch. pluto** *sp. n.* (176 i). Antennae, head and thorax black, orbita white. Palpi black strewn with few white scales, appearing grey. Abdomen black, a white lateral line begins narrow on the first segment, widening rather much in the middle and ending narrow again on the last segment; easily discernible from any other species by this line. Legs black, posterior tarsi slightly ringed black and white. Forewing black with a very indistinct wedge-area and a small distal area, crossed by three veins. Hindwing hyaline, veins and margins as well as the rather long fringes of all the wings black. On the under surface the abdomen is brownish black, the costal margin of the forewing dingy yellow, the distal area grey, crossed by black veins. Evidently allied to "*Syn.*" *hispidus* *Druce*. 22 mm. 1 ♀. March. Brazil, Minas, Araguay, leg. Prof. SEITZ. Type: Senckenberg Museum.

aurata. **Ch. aurata** *Hy. Edw.* is a doubtful animal; it is said to be like the European *Ch. annellata* *Z.* (Vol. II. pl. 51 g). It was either imported or the label was exchanged. Panama.

penthetria. **Ch. penthetria** *sp. n.* (176 i). Antennae, palpi, head and thorax black. Abdomen black, bluish black beneath. Anal tuft black, two narrow oblong lateral appendages of a bright golden yellow. Legs black, hind tibiae rather strongly haired. Forewing black, fringe oscillating. Hindwing transparent, veins and fringe black. 22 mm. Brazil, Ypiranga. April. ♀ collected by Prof. SEITZ. Type: Senckenberg Museum.

12. Genus: **Conopia** *Hbn.*

Head small, palpi short and straight. Antennae club-shaped, pointed towards the end. Abdomen slender. Posterior fomora with short hair. Forewing with 12 veins, 7 and 8 stalked. Hindwing pointed at the apex, veins 4 and 6 stalked, 7 and 8 absent. Type: *C. praecedens* *Hy. Edw.*

praecedens. **C. praecedens** *Hy. Edw.* (176 i). Head and thorax brownish black, the latter with red stripes on each side. Antennae orange with black tips. Abdomen black, with a few red scales laterally, the last 3 segments and the anal tuft beautifully lemon-coloured. Legs reddish orange with a broad black band on the tibiae, posterior tarsi lemon-coloured. Forewing brown with a narrow transparent streak which turns reddish, ending in the centre of the wing. Hindwing brown, transparent at the base. Both wings beneath striped red and yellow. 30 mm. North Carolina. It was described as *Palmia*.

sequoiae. **C. sequoiae** *Hy. Edw.* (= *superba* *Hy. Edw.*, *pinorum* *Behr*) (176 i). Head black, palpi yellow, outside black, collar yellow, antennae black. Thorax black with a very narrow yellow lateral line widening behind, adjoining a yellow transverse streak. Abdomen black, all the segments, except the 1st and 3rd, with lemon-coloured rings above and below. Anal tuft black, yellow beneath. Legs yellow and black, anterior coxae yellow, femora black outwards, tibiae yellow, tarsi yellow with black bands. Forewing transparent with very narrow black margins and discal mark. Hindwing with narrow black margins, inner margin yellowish. 24 to 30 mm. California (Mendocino Co) and Washington. — Larva in old trees of *Sequoia sempervirens*, *Pinus ponderosus*, *Pinus lambertina*; it does much harm to the forests of Mendocino County, California. The eggs are deposited in the nooks of twigs, the larva works itself in curved passages into the twigs and trunks, which is indicated by excretions of resin on the attacked parts of the tree. As the insect is not rare, the destructions may often be rather considerable. The larva often spins a cocoon already in December and January; the imago appears chiefly in June and July.

exitiosa. **C. exitiosa** *Say* (= *persica* *Thom.*, *pepsidiformis* *Hbn.*, *xiphiaeformis* *Bsd.*) (177 g). ♂: head blackish steel-blue, yellow between the eyes. Palpi yellow beneath, black above. Collar yellow in front. Antennae black. Thorax deep steel-blue with yellow patagia and a posterior yellow transverse blotch, a yellow spot at the base of the forewing beneath. Abdomen blackish steel-blue with narrow yellow rings on the front sides of the segments; these rings may sometimes also disappear. Anal tufts black, laterally whitish. Legs steel-blue, tibiae with yellow spots, tarsi yellow beneath, anterior coxae yellow. Forewing transparent, opalescent

with narrow black margins and a similar discal mark, the posterior margins strewn with yellow; the yellow predominates more beneath. Hindwing transparent, distal margins blackish blue, costal margin yellowish. ♀ very different from the ♂. Head, antennae, palpi, thorax and legs deep blackish blue, abdomen the same, the 4th segment quite reddish orange, traces of red may also occur on the 5th segment. Forewing deep bluish black or violettish black. Hindwing transparent, blackish blue near the base, the not very narrow margins and fringe likewise blackish blue. 18—32 mm. Canada, Maine to Florida and Texas, to the west as far as the Rocky Mts. This so-called “peachtree-borer” is one of the best known and most hated insects of the United States. — The eggs are deposited on the trunk near the soil. The larva lives underneath the bark and produces gummous secretions; it pupates in a cocoon spun of wood-remnants and clods of mud. The imago appears already in April in the south, the farther to the north the later, until October; it chiefly appears in June and July. The wild cherry seems to have been its original food-plant, from which it passed over to the cultivated plants; peach-trees are most preferably attacked, besides plums, almonds, apricot-plums, spore-apples (*Amelanchier canadensis*) and beach-plums. — ab. *fitchii* Hy. Edw. is the ♀ form exhibiting, like the type form, *fitchii*, the 4th segment reddish orange and the space between the two interior veins dusted over with black, so that the transparent part of the wings is cut in two parts. — ab. *edwardsii* Beut. is like the preceding form, but the *edwardsii*, 5th segment is also reddish orange. — var. *luminosa* Neum. ♂: like the type form, but the margins of the *luminosa*, wings are densely covered with yellow scales, owing to which the insect looks very peculiar.

C. opalescens Hy. Edw. (= *pacifica* Riley) (177 h). ♂: head, thorax and abdomen black. Legs black *opalescens*, with white tufts. Forewing transparent with black margins, cross-vein and distal margin broad. Hindwing transparent with black margins; beneath the same. ♀: head, thorax abdomen and legs blackish bronze. Forewing metallic greenish black. Hindwing transparent opalescent, distal margins and fringe metallic bluish black or greenish black; under surface the same. 25—34 mm. Nevada, California, Washington, Oregon. May, June. — The larva lives like *exitiosa* in the trunk and roots of peach, cherry and apricot and may occasionally also do much harm.

C. graefi Hy. Edw. (177 h). ♂: head black. Palpi yellow beneath, black above. Collar in front edged *graefi*, with yellow. Antennae black. Thorax bluish black with a very narrow yellow line on the patagia and the posterior part. Abdomen bluish black with narrow pale yellow rings on each segment. Anal tuft white. Legs bluish black with yellowish tufts. Forewing transparent opalescent, with a narrow costal and inner margin, the latter scaled yellow, but with a broad black distal margin and a similar cross-vein. Under surface dusted yellow. Hindwing transparent with a narrow violet margin and cross-vein. ♀: head, palpi, antennae, legs and thorax quite black, sometimes violettish black, abdomen quite black, forewing deep violettish black or greenish black with traces of a darker discal mark. Hindwing transparent with a narrow violet margin and cross-vein, sometimes the cell slightly scaled black. 22—28 mm. Colorado, Nevada, Washington. July, August. — Larva in spring in the roots of wild cherry. — var. *barnesii* Beut. (177 h). Like the type form, but the 4th segment is *barnesii*, orange, by which it resembles the ♀ of *exitiosa* (177 g). 28 mm. Colorado.

C. peruviana Rothsch. (177 h). ♀: legs and under surface of body golden yellow. Head, palpi and an- *peruviana*, tennae black. Thorax black with golden yellow margins. The first 4 abdominal segments above black, laterally golden yellow, segments 5 and 6 golden, the rest black. Forewing yellowish hyaline, veins, inner margin and discocellular band golden yellow, the remaining quarter black. Hindwing yellowish hyaline. Veins, anal margin golden yellow, the rest of the margin black. Marcapata, Eastern Peru. 1200 m.

C. angarodes Meyr. Head bluish black, orbita white. Antennae black. Palpi black, white beneath. *angarodes*, Thorax purple black, a reddish orange stripe on each side, sternum orange on each side. Abdomen bluish black, striped white beneath. Anal tuft long, purple. Wings hyaline, veins black, fringe brownish. Forewing with a bluish black costal streak, cross-vein black, a broad black distal margin, slightly yellowish ochreous in front. Hindwing with a colourless cross-vein and black margins. 20 mm. Manaos, Brazil. November. 1 ♂.

C. xanthomelanina sp. n. (178 e). Antennae yellowish brown, clubs black. Head, thorax, abdomen *xanthomela-* brownish black, anal tuft black in both sexes, in the ♂ laterally and beneath with traces of yellow. Palpi and *nina*, collar yellow, silvery white before the eyes. The 1st and 5th abdominal segments in the ♂ very finely margined with yellow, the ring of the 5th extending all around the body; the ♀ with traces of rings, but distinctly discernible on the 4th segment. Legs chiefly yellow, the forelegs darker, the ends of the hind tibiae black. Forewing transparent, margins and veins brownish black, in the ♂ with a moderately broad distal margin which is very broad in the ♀ so that the distal area is only narrow, traversed by 4 veins, anal margin in both sexes broadly yellow like the broad discal vein which is finely edged with dark outside and inside, by which it is easily distinguishable from many other species. Hindwing transparent, veins and margins blackish brown, fringes of all the wings yellowish brown. 21 mm. 1 couple. Itatiaya, Brazil, December, January. Type: Coll. MARTEN.

xanthonympha. **C. xanthonympha** *Meyr.* Head and thorax yellow. Face laterally white. Palpi yellow. Antennae black, yellow below. Abdomen yellow, segments black without the margins. Anal tuft orange with a black central spot. Wings hyaline, veins black, fringe yellowish, with brownish basal and apical shadows; forewing with a black costal streak, a yellowish anal margin, a black cross-vein distally edged with yellow, a black distal margin, yellow before it, traversed by the dark veins. Costal margin of hindwing yellow, the following veins yellow, cross-vein colourless. Hind tibiae yellow with a black lower apical spot, tarsi blackish with yellow scales at the end of the 1st joint. 17 mm. Parà, Brazil. June. 1 ♀.

dasyproctos. **C. dasyproctos** *sp. n.* (178 d) is allied to *xanthonympha* *Meyr.* Antennae black, pale yellow below, base intensely yellow, a metallic violettish blue gloss between. Palpi, pectus and anterior coxae yellow; edged white before the eyes. Head and thorax black, the latter with three yellow longitudinal stripes. Abdomen above and beneath pale golden yellow, warming into brownish, darker at the base; the last joints are fusiformly compressed, passing over into the broad and strong dingy yellow anal tuft which, seen from the side, appears to be obliquely cut off from in front to behind. Legs quite yellow. The wings as in *xanthonympha*, the distal area of the forewing slightly, but especially the wedge-area from the discal vein towards the base provided with a distinct dark shadow. 20 mm. Brazil, Bahia. Type: Berlin Zool. Museum.

rotaria. **C. votaria** *Meyr.* Head and thorax greenish blue, iridescent. Face and orbita white. Palpi yellowish, dark brownish at the end. Antennae purple black. Abdomen dark indigo blue, base whitish, posterior margins of segments 5 and 7, sometimes also of 6, white, all the segments beneath more or less margined with white, anal tuft deep purple, mixed with white at the beginning on each side. Wings hyaline, veins black, fringe dark brown, cross-vein purple black, the rather broad distal margin also purple black. Hindwing with a colourless cross-vein, a narrow dark brown streak growing thicker towards the apex. Forewing beneath speckled whitish at the apical spot. Parà, Brazil. January, June, July. Only ♂♂ are known.

scarabitis. **C. scarabitis** *Meyr.* (178 e). Head and thorax dark blue, collar yellow. Palpi black, whitish in front. Antennae black. Abdomen blackish green, anal tuft dark blue. Wings hyaline, veins black, fringe dark brown. Hindwing with black veins and margins, cross-vein colourless. 14 mm. 1 ♂. Peru, Jurimaguas. March.

13. Genus: **Ichneumenoptera** *Hmps.*

Palpi relatively short and straight. Antennae long and plain. Legs bare. Abdomen longer than in *Conopia*. Forewing without vein 2, the fork of 7 and 8 is shorter. Veins 3 and 4 of hindwing stalked, 6 arises near the upper angle of the cell. On the whole very similar to *Conopia*, but the abdomen and anal tuft are always longer. Type: *I. auripes* *Hmps.* (Vol. X, pl. 94 d) from Asia.

caeruleifascia. **I. caeruleifascia** *Rothsch.* (178 e). Legs steel-blue, anterior tarsi white, hair-tufts of the posterior tibiae and the first half of the tarsi steel-blue, edged with white. Palpi white. Antennae, head, thorax and abdomen steel-blue, discal band bright metallic blue. Hindwing whitish hyaline, margins and a broad discocellular spot steel-blue. 25 mm. Marcapata (Eastern Peru). 1200 m.

14. Genus: **Leptaegeria** *Le Cerf.*

The 2nd and 3rd joints of the palpi very long. Antennae thick and short, finely and shortly dentate. Proboscis normally developed. Body long, cylindrical. Legs long and neat, not with projecting hair. Anal tuft composed of two straight and oblong brushes. Forewing long and narrow, veins 2 and 3 are close together at their origin, 7 and 8 are stalked on half their length. Hindwing oval, without a very prominent anal lobe. Veins 3 and 4 on a short stalk, 7 absent. Type: *L. flavocastanea* *Le Cerf.*

flavocastanea. **L. flavocastanea** *Le Cerf* (178 e). Head brown, bright, mixed with yellow in front, edged with white around the eyes. Palpi yellow with a small black spot at the base. Antennae blackish brown, reddish yellow near the base below. Collar brownish bronze. Thorax chestnut brown, patagia yellow, metathorax yellow above and beneath. Abdomen chestnut brown, darker towards the end, turning almost blackish bronze, 1st segment broadly yellow, whitish beneath. Anal tuft dark. Legs quite yellow except the hind tibiae which exhibit one red-brown spot each at the end. Forewing transparent, the margins, veins and discal vein brownish bronze, the distal area dusted with the same colour. Hindwing transparent, veins and margins brownish bronze, fringes of all the wings greyish brown. 22 mm. Bolivia: Cochabamba. Only 1 ♀ is known.

axiomnemonauta. **L. axiomnemonauta** *sp. n.* (178 e). Antennae dark rusty brown. Head, thorax and abdomen deep brownish black, almost black. Palpi light yellowish grey, the 2nd joint below with light grey hair. Legs from light ochreous to golden yellow, the coxae blackish brown, the hind tibiae with a small faded dark brown spot outside at the end. The penultimate abdominal segment exhibits a fine silvery grey ring continued beneath in a broad spot. Anal tuft enormously developed; seen from the side, it is obliquely cut off from above to below; with grey hair in the middle, otherwise brownish black, of more than half the length of the abdomen. Forewing

rusty brown, costal part darker, an oblong spot at the anal angle hyaline. Hindwing hyaline, veins and margins brownish black. Fringe lighter greyish brown. 32 mm. Bolivia: Rio Songo (Yungas), 1200 m. 1 ♀. Type: Berlin Zool. Museum.

L. cillutincariensis *sp. n.* (178 f) at first sight resembles *Aegerina vignae* Busck., but it has normally developed palpi and a different neurulation, owing to which it is placed to *Leptaegeria*. Antennae, head, palpi and thorax black, a silvery white spot before the eyes. Thoracal marking not discernible. Abdomen black, the 2nd to 6th segments finely margined with light yellow behind, closing together on the ventrum, where the 2nd and 4th become broader. Anal tuft black. Legs blackish brown, tarsi lighter. Forewing transparent, margins light brown, veins blackish brown, a dark semihyaline apical shadow, the narrow discal vein bordered outwardly with reddish orange. Hindwing transparent, veins and margins, as well as the fringes of all the wings brownish grey 28 mm. Bolivia, Cillutincara, 3000 m. January. Type: Berlin Zool. Museum.

15. Genus: **Osminia** *Le Cerf*.

Head slightly broader than the thorax. Palpi oblong, hairy, but not projecting, the 3rd joint very small. Proboscis well developed. Antennae long and thick, plain. Body strong and long, terminating into a large bipartite anal tuft. Legs middle-sized, the posterior ones shorter than the abdomen. Forewing straight, slightly roundish at the apex, vein 2 arises before the interior angle, 3 from the latter, nearer and parallel to 2, 4 at the base very near to 5, 7 and 8 stalked on half their length, 9 from the anterior angle of the cell, 10 and 11 distant from the base, confluent at $\frac{1}{4}$ of their course. Hindwing broad and round, vein 1 fine and short, 2 arises at $\frac{3}{4}$ from the radial vein, 3 and 4 from the interior angle of the cell, stalked on $\frac{1}{5}$ of their length, 5 from the angle of the cell, 7 absent. Type: *O. ferruginea* *Le Cerf*.

A. ferruginea *Le Cerf* (178 f). Head black, mixed with iron brown and white, palpi black, whitish in front. Antennae black above, brownish beneath. Collar iron brown. Thorax black with fine brown scales. Abdomen purple black above, with a brownish tinge; the margins of the segments very bright, a pale yellow spot on the 4th segment and one at the base of the 5th. Anal tuft strong and broad, almost quadrangular, brownish above, almost black beneath. Legs black and brown. Forewing transparent, costa, anal margin, veins and discal vein steel-black, distal area traversed by 4 veins. Hindwing transparent, with a slight blue reflection, veins and margins purple black. Fringes of all the wings bronze black. 25 mm. Mexico. Region de Cordoba. Only 1 ♂.

16. Genus: **Stenosphaecia** *Le Cerf*.

Head of medium size, convex. Palpi long, the 3rd joint longer than half of the 2nd, proboscis well developed. Body strong; abdomen cylindrical, more than twice as long as the thorax. Legs middle-strong, the posterior ones not longer than the abdomen. Wings long and broad; vein 1 of forewing well developed, not divided at the base, 2 very close to the origin of 3, 4 nearer to 5 than to 3, 7 and 8 stalked on $\frac{2}{3}$ of their length, 9 from the anterior angle of the cell, 10 and 11 divided at the base, united at about $\frac{1}{3}$ of their length, then divided again in their last third. Hindwing: vein 1 very fine, 2 a little before the interior angle of the cell, 3 and 4 from that angle and stalked on $\frac{1}{5}$ of their length, 5 from the cell, 6 absent, 7 from the anterior angle of the cell. Type: *S. columbica* *Le Cerf*.

S. columbica *Le Cerf* (180 f). Head brownish black. Palpi bronze brown, with much white above and outside. Antennae bronze brown. Collar, thorax and abdomen bronze brown, abdomen lighter beneath; anal tuft brown. Legs quite bronze brown, tarsi whitish inside. Forewing bronze brown at the base and on the very broad discocellular streak, the three hyaline areas very small, the exterior one twice higher than broad, traversed by 4 veins, the distal margin broad and less scaled. Hindwing transparent, the thick discal streak, the margins and veins bronze brown, fringes of all the wings greyish bronze. 30 mm. Colombia, Santa Fé de Bogota. The type is a ♀.

17. Genus: **Teleosphaecia** *Le Cerf*.

Head small and round. Palpi twice longer than the head. The 2nd joint twice longer than the 1st and 3rd together, the last pointed and directed upward. Antennae fine. Proboscis well developed. Wings completely covered with semitransparent scales. Legs medium sized. Anal tuft short and straight. Forewing long and broad, veins 7 and 8 stalked on half their length, 10 absent. Hindwing oval, discal vein very slanting, vein 1 rudimentary, 2 near the interior angle of the cell, 3 and 4 on a short stalk from that angle, 7 absent, 8 near the cell at the base and withdrawing much from 6. Type: *T. bibio* *Le Cerf*.

T. bibio *Le Cerf* (178 f) is a small peculiar species easily discernible by the unicoloured dull brownish black colouring. Head black, traces of yellow hairs in the neck, white before the eyes. Palpi black, 1st joint white beneath. Collar, thorax and abdomen above and beneath bronze black except the last segment which is slightly scaled white. Legs black. Forewing semitransparently covered with small brownish black scales, hindwing the same except the basal region remaining hyaline. Fringe black. 21 mm. Bolivia, Cochabamba, 1 ♀.

unicolor.

T. unicolor Wkr. ♂: head black, slender. Palpi whitish beneath. Antennae not provided with hooks, smooth. Abdomen slender, more than thrice as long as the thorax. Anal tuft quadrangular. Hindlegs strong, spurs very long. Wings narrow, strewn with dark green scales, a narrow discal vein. 18 mm. Ega.

18. Genus: **Sannina** Wkr.

Palpi erect, covered with scales not with hair as far as the height of the head, the 3rd joint long. Antennae long, filiform. Hind and middle tibiae covered with short hair. Last segment of the male abdomen with four long divaricating brushes proceeding from the base, and a fifth long one at the end of the segment. Veins 7 and 8 of forewing stalked. 7 and 8 of hindwing short. Type: *S. uroceriformis* Wkr.

uroceriformis.

S. uroceriformis Wkr. (= *uroceripennis* Bsd., *quinquecaudata* Ridings) (178 f). Head, palpi and antennae deep bluish black. Thorax deep bluish black with a red lateral stripe. Under surface and legs woolly bluish black, the 4th segment more rarely, the 5th and 6th above deep orange red, in the ♀ only the 4th segment. The anal tufts bluish black, absent in the ♀. Forewing unicoloured bluish black, hindwing the same, though with a narrow hyaline area at the base. 18—32 mm. From Virginia to Florida, to the west as far as Kansas and Montana. Larva in the roots of the date-plum, 40—50 cm underneath the soil.

verruugo.

S. verrugo Drc. (178 f). Forewing dark reddish orange, black at the base and apex, fringe of the distal margin broad and black. Hindwing somewhat lighter orange, slightly hyaline, fringe black from the apex to the anal angle. Head, thorax, abdomen, palpi, antennae and legs glossy black. 38 mm. Mexico, Esperanza. ENGELHARDT presumes *verruugo* to be the ♀ of *Alcathoe korites*.

cryptiformis.

S. cryptiformis Wkr. Black, head behind with yellow hair. Antennae filiform, dentate below, very much longer than the thorax. Tibiae with brownish yellow spurs. Wings transparent with black purple fringes. Distal margin of forewing brown, costa and transverse band purple black. 20 mm. Patria uncertain, presumably South America. The type is a ♂. Not being mentioned in any fauna, it is quoted here.

19. Genus: **Sphecia** Hbn.

Separated from *Aegeria* by the invariably present tongue and veins 4 and 5 of hindwing being always stalked. Hind tibiae longer and stronger haired than in *Aegeria*. Type: *S. crabroniformis* Lewin from Europe.

pacifica.

S. pacifica Hy. Edw. (= *californicum* Neum.) (178 g). Head black. Palpi yellow. Antennae brownish black, lighter beneath. Legs yellow. Thorax deep brown, in front with a yellow line on each side, angularly extending hindward. A few black and yellow hairs between the thorax and abdomen, the shoulder-spot at the origin of the forewing is likewise yellow. The 1st and 2nd abdominal segments blackish, the 2nd yellowish in front, the others beautifully yellow, the 3rd narrowly black in front, the 3rd and 4th dusted over darker, though the yellow is well visible. Under surface quite yellow. Wings transparent, narrowly margined with brownish orange like the discal mark of the forewing. 25—40 mm. Nevada, Montana, California and Washington.

tibialis.

S. tibialis Harris (= *flavitibia* Wkr., *minimum* Neum.) (178 g). ♂: head black, orbita, sides, and palpi yellow. Antennae black. Thorax brownish black with a very narrow yellow line on each side, passing over behind into yellow hair-tufts. A yellow dot at the base of the forewing. The 1st abdominal segment black, more or less broadly yellow behind, the 2nd quite black, the 3rd black, yellow behind, the 4th quite blackish brown, the others blackish brown with posterior yellow rings. Anal tuft black and yellow. Legs yellow mixed with brown. Forewing transparent, veins, discal mark and margins brownish orange or also deep blackish brown. Hindwing transparent, otherwise like the forewing. ♀: stronger than the ♂, the yellow markings more intense, the yellow lateral lines on the thorax bend round in front forming an angle, so that they meet the yellow spot at the base of the forewings. The 1st to 4th abdominal segments as in the ♂, the last three segments mostly quite golden yellow, the 5th and 6th half yellow, half brown; beneath yellow with narrow brownish black bands, except the last segment or also the two last segments which are quite yellow. 30—40 mm. Canada, New England, New York, British Columbia, Vancouver, Colorado and California; July, August. — The larva lives in

dyari.
anonyma.

the trunks of willows and poplars. — ab. ♀ **dyari** Cock. Thorax brownish black, lateral lines in front very broad, then very narrow, the posterior dorsal spot very broadly yellow. — var. **anonyma** Strd. (178 g). Abdomen with more yellow, especially the last 3 segments almost entirely yellow. The 1st segment black, the 2nd black, narrowly yellow at the base, the 3rd yellow, narrowly black at the apex, the 4th black, narrowly margined with yellow at the base, the 5th and 6th yellow, narrowly black at the apex; apex of abdomen cinnamon brown. Las Vegas, New Mexico. Beginning of July.

dasypodiformis.

S. dasypodiformis Wkr. ♂: black. Palpi yellow beneath, red at the apex. Antennae with black dents. Prothorax with a yellow margin. Abdominal segments with yellow bands. Legs dingy yellow, femora mostly black, hind tibiae more thickly covered with hair than in the European species. Wings transparent, fringes

short, blackish coppery, veins rust-coloured; forewing purple black along the costa, the fork of the 2nd upper vein shorter than in *apiformis*. 30 mm. Presumably Central and South America.

S. championi Drc. (178 h). ♂: all the wings hyaline, costal and inner margins black. Discal vein outwardly reddish yellow, the exterior hyaline area and the whole hindwing golden yellow hyaline, fringe and veins black. Palpi yellow beneath, reddish at the tips. Antennae red-brown. Thorax black, collar and tegulae yellowish. Abdomen black, segments with yellow bands. Legs reddish yellow. ♀: similar to ♂, but the forewing dark brown except an area at the anal angle remaining hyaline. 32–38 mm. Guatemala, near the town. *championi*.

20. Genus: **Aegerina** Le Cerf.

Head small, slightly convex. Palpi erect, the two last joints long and densely haired. Proboscis well developed. Antennae rather short, fusiform. Thorax strong. Abdomen of ♂ slim, of ♀ cylindrical with a rather long anal brush. Legs delicate, hindlegs shorter than the abdomen. Forewing long and stretched; vein 1a short, not divided at the base, 2 arises a little before the interior angle, 3 from the latter, 4 equidistant from 3 and 5; 7 and 8 stalked on $\frac{2}{3}$ of their length, 9 absent, 10 and 11 very near and parallel. Hindwing: 1 a very fine, 2 arises a little before the interior angle of the cell, 3 and 4 on a short stalk, 5 from the angle of the cell, 6 absent. Type. *A. ovinia* Drc.

A. ovinia Drc. (178 h). Forewing bluish black with a hyaline streak along the inner margin. Hindwing whitish hyaline, veins black, fringes of both wings blackish brown. Head, palpi and antennae black. Thorax and abdomen glossy bluish black, the 4th segment broadly edged with pale yellow. Anal tuft broadly black with a few grey hairs laterally. Abdomen beneath white. Legs black, with grey bands. 30 mm. Mexico, Coatepec. *ovinia*.

A. mesostenos sp. n. (178 h) is closely allied to *ovinia* Drc., but smaller, only 20–21 mm. Only the 2nd abdominal segment above finely margined with white, beneath broadly light creamy white. Legs black, a few white hairs on the joints of the hindlegs, the hind tibiae with 4 long spurs. Otherwise very similar to *ovinia*. Brazil, Viannopolis. March. 1 couple collected by Prof. SEITZ. Type: Senckenberg Museum. *mesostenos*.

A. vignae Busck. The 2nd palpal joint with a triangular black scale-spot, mixed with yellow, the last joint erect, black with a reddish apex. Antennae gradually thickened with a small hair-pencil at the end, in the ♀ plain, basal halves bluish black and apical halves dark brown, in the ♂ reddish brown, dentate below. Head dull black with a slight transverse line of yellowish white scales. Thorax dark red-brown, almost black, shoulders and behind transversely bordered with yellow. Abdomen strangulated wasp-like near the base, bluish black, each segment behind narrowly margined with yellow. Anal tuft bluish black. Forewing with a bluish black costal margin, inner margin and discal vein scaled reddish brown, the rest transparent, veins 11 and 10 absent, 7 and 8 stalked to the costa, 2–6 separated. Hindwing transparent, legs metallic bluish black, spurs and posterior margins of each joint yellow. Bahia (Brazil). Larva in the stalks of *Vigna sinensis* and other cultivated Leguminosae. *vignae*.

A. alomyaeformis sp. n. (178 i). Antennae black, the first joints yellowish, apically brownish; ciliated below in the ♂. Head and thorax black, the latter with light yellow stripes on the posterior part of the patagia, metathorax slightly light yellow. Abdomen above and beneath with the 1st segment black, powdered with rusty brown, the 2nd, 3rd and 4th beautifully rusty brown, the posterior margin of the 4th with a fine light yellow band, the last joints as well as the anal tuft black. Legs rusty brown, hind tibiae with four equal moderately long spurs. Wings as in *mesostenos*, but the margins browner. 21–22 mm. Brazil. Araraquara and Rio Preto (São Paulo, Brazil). 1 couple collected by Prof. A. SEITZ. Type. Senckenberg Museum. *alomyaeformis*.

A. allotriocho sp. n. (178 i). Antennae, palpi, head and thorax bluish black. The palpi exhibit the generic peculiarity (the 2nd and 3rd joints strongly haired) immensely developed, so that one might think of the presence of biting mouth-organs. Abdomen as in *vignae* strangulated wasp-like at the base, the 1st segment bluish black, the 2nd brown, spotted yellow at the posterior margin, all the others inclusive of the pointed anal tuft dingy reddish orange (almost vermilion); beneath the same, only the basal joints are yellowish here. On the 5th and 6th segments there are at equal distances four small raised yellowish hair-tufts forming a quadrangle. All the legs blackish blue, hind tarsi yellowish and black. Forewing thinly scaled greyish yellow, transparent, costal vein dark brown, the inner margin at the base narrowly hyaline like the anal angle, too; a small dingy white spot at the costal vein, shortly before the apex. Hindwing transparent, a dark shadow at the costal vein, veins black; fringes of all the wings brownish grey. 35 mm. The total impression of the insect is that of a wasp owing to the red abdomen, the semihyaline wings, and especially the enormously haired palpi. Brazil, Villa Bella. 1 ♀. Type. Berlin Zool. Museum. *allotriocho*.

21. Genus: **Aegeria** F.

Head small, palpi erect, but scarcely reaching to the height of the head, covered with long hair. Antennae short and thick, pectinated in the ♂, plain in the ♀. Body strong, cylindrical with a truncate end, ♂ with

a small anal tuft. tibiae thickly covered with short hair, femora and tarsi hairless. Tongue absent. Forewing with stalked veins 7 and 8. Hindwing: veins 4 and 5 from the angle of the cell or from a very short stalk, discocellular vein very oblique. Type: *A. apiformis* Cl. from Europe.

apiformis.

A. apiformis Cl. (= *vespiformis* Hufn., *crabroniformis* Den. & Sch.) (Vol. II, pl. 51 a). Head and palpi lemon-coloured. Antennae black above, reddish yellow beneath. Thorax brown, in front with a large yellow spot on each side, behind with a smaller diffuse spot. Abdomen with very broad yellow bands on the anterior margins of the segments, the last 2 quite yellow, segments 1 and 3 brown. Legs dark yellow with brown. Forewing transparent with narrow brown margins and discal mark, hindwing the same. 30—45 mm. United States to the west as far as Nevada; Europe-Siberia. Larva in the lower parts and roots of older poplars and willows, living two years. Imago in June and July. Not common in America, contrary to the Old World where it is rather common. It can no more be ascertained whether the insect is autochthonous for America or was imported from Europe.

22. Genus: **Euryphrissa** Btlr.

Hindwing and abdomen broader than in *Synanthedon*, the second pair of legs densely covered with long scales, but scantily haired. with two robust, long, divergent terminal spurs. The hind legs are rather short, tibiae densely covered with long scales, prolonged beyond the middle at the outer margin with a broad hair-brush of 2 mm length, two long central and two shorter terminal spurs. Type: *E. plumipes* Wkr.

plumipes.

E. plumipes Wkr. ♀: deep black, strong, blackish purple beneath. Face white. Palpi erect, silvery white, black apically. Antennae slender dingy ochreous below. Abdomen more than twice as long as the thorax, narrowing down towards the end. Legs short, strong, with blue or purple scales, hind tibiae fringed black, decorated with a very dense hair-tuft of a pale yellow colour at the end, tarsi golden yellow. Wings transparent, fringes purple. Forewing with a dingy dark yellow inner margin, the costa and cross-vein purple. 18—20 mm. Ega.

syngenea.

E. syngenea sp. n. (178 i). Size and total habitus like that of *plumipes* Wkr. Head black, palpi yellow, darker apically. Antennae shorter with thicker clubs than in *plumipes*, yellowish brown. Thorax blackish blue with a yellow dorsal line and two lateral ones, metathorax with yellowish hair. Abdomen blackish blue, the posterior margins of all the segments more or less finely margined with yellow, beneath all is yellow except the 3rd and 4th segments remaining black. Legs predominantly yellow, the hair of the posterior tarsi black, not so prominently tuft-like as in *plumipes*. Wings as in *plumipes*. Brazil (Rio Grande do Sul) and Peru (Pebas). 2 ♀♀. Types: Berlin Zool. Museum.

23. Genus: **Myrsila** Bsd.

Antennae filiform, without the least thickening at the end. Palpi long, bare, very pointed. Proboscis small and short. Legs very long with long and strong spurs. Abdomen pointed like that of a *Pompilida*. Wings long and stretched with little developed fringes.

auripennis.

M. auripennis Bsd. (178 i). Head, palpi and antennae of a bright black colour. Thorax pale rust-coloured turning blackish. Anterior part of abdomen pale red, posterior part black, without a reflection. Hindwing dotted white on the fringe. Legs black, anterior part of the hind tibiae pale reddish orange. Beneath more pale red. 24 mm. Brazil: Pará, Amazons.

24. Genus: **Alcathoë** Hy. Edw.

Palpi rather erect, as far as the height of the head, 2nd joint very long, 3rd joint very short. Antennae uniform, tapering at the end, slightly dentate in the ♂, plain in the ♀. Posterior tibiae with a hair-tuft at each end and a similar tuft at the base of the tarsi, near the tibiae. Forelegs and middle legs without hair-tufts. Abdomen of ♂ with a long tail-like hairy appendage dividing the anal tuft. Tongue present, but feebly developed. Forewing with 12 veins, 7 and 8 stalked. Hindwing: vein 2 from the cell, 4 and 5 on a short stalk, 7 and 8 coalescent, discal vein straight. Type: *A. caudata* Harris.

caudata.

A. caudata Harris (= *cordata* Ril. & How.) (179 a). ♂: head black, face dull reddish. Palpi, collar and antennae orange. Thorax violet or dark brown. Abdomen black with a violet reflection, orange below. Anal tuft black, the tail-like appendage bright orange. Legs orange, middle and hind femora black like the ends of the hair-tufts at the end of the tibiae. Forewing violet, transparent from the base almost to the centre, discal vein sometimes slightly dusted orange. Hindwing transparent with an intense reflection, the discal mark, the very narrow distal margin and the fringe violettish black. ♀: head black, palpi and collar orange. Thorax and abdomen above and beneath black. Forewing violet, blackish at the base. Forelegs orange, coxae black, middle

and hind legs black with orange tarsi. 20—32 mm. Canada, New England and Central States, to the south as far as Florida, to the west as far as Ohio, Illinois and Michigan. — var. *walkeri* Neum. (178 i). Head, abdomen and tail-appendage all black, without any trace of orange. Legs black, tibiae orange. Antennae above black, beneath and the tips dull orange. Wings like those of the type. New York. — The larva lives in the roots and the root-crown of *Clematis virginiana* and *vitalba* and presumably also of allied *Clematis* plants, often several in one plant. They pupate in a cocoon in the passages, the imago appearing in the north from June till August, in the south already from April.

A. korites Drc. Head black, palpi reddish orange beneath. Antennae orange with more or less black scales. Thorax and abdomen black with a blue reflection, a few red places at the posterior end of the patagia and in the centre of the thorax. Anal tuft and tail-appendage black. Legs black. Forewing with orange scales, the costa, median vein and submedian vein black. Fringe brown. Hindwing orange with a round hyaline spot at the anal margin, veins black. The ♀ shows the red and orange colouring less developed, otherwise similar to the ♂. 25—28 mm. Durango, Colorado, Guatemala, Costa Rica. Larva in roots of *Clematis ligustrifolia*.

A. carolinensis Engelh. Antennae absent, the stumps orange. Palpi black, with orange hair in front. Head, thorax and abdomen black with a blue reflection. Anal appendage orange, lateral tufts black. Forewing and hindwing black with a blue reflection, forewing with a narrow transparent area near the base, hindwing with a broader one near the base, divided by the veins A 1 and A 2. Legs black, middle tibiae and anterior part of the tarsi of the hindlegs densely covered with black hair, interrupted inside by orange. Hitherto only 1 ♂ known. Black Mountains, North Carolina. Taken on *Clematis* blossoms in summer.

A. pepsoides Engelh. Antennae orange, more or less covered with black scales, in the ♀ quite orange. Palpi above black, beneath black mixed with orange. Head, thorax and abdomen black with a coppery gloss and a few red scales on the patagia and mesothorax. Anal appendage and lateral appendage black. Legs black. Forewing orange, costa, submedian vein and median vein with black beyond the cell, fringe blackish brown. Hindwing orange with a round hyaline spot in the anal region, veins partly black. 26—35 mm. Colorado, Utah, New Mexico, Nevada, Arizona, California. In the south in May, in the North until August. Larva in *Clematis ligustrifolia*. — subsp. *atra* Engelh. Antennae black above, brown below. Head, thorax, abdomen, anal appendage and legs black. A round hyaline spot in the anal region of the hindwing. 29 mm. Jemez Springs, New Mexico, 2400 m. August.

A. altera sp. n. (179 a). Head black, light yellow before the eyes. Antennae half black, then gradually orange, the tips suddenly again black. Thorax and abdomen brownish black, the base darker. Anal tuft orange. Legs orange, the hair-tuft at the end of the hind tibiae darker. All the wings yellowish hyaline, the moderately broad costal margin, the discal mark and veins black. Easily discernible from all the other *Alcathoe*-species hitherto known by the hyaline wings. 28 mm. Mexico. 1 ♂. Type: Berlin Zool. Museum.

25. Genus: **Tarsopoda** Btlr.

Wings with longer fringes than in *Synanthedon*. Palpi more erect. Tibiae and tarsi of the 2nd and 3rd pairs of legs densely covered with compressed fan-like feather-scales. Type: *T. renipes* Btlr.

T. renipes Btlr. Wings hyaline, veins black, forewing with a rosy tinge, costal margin purple black, discal band, distal and inner margin brownish bronze, fringe pale brown; hindwing with brownish bronze distal margin and fringe. Body above and beneath brownish bronze. Palpi and collar, coxae of the first pair of legs steel-blue; femora, tibiae and tarsi absent; femora of the 2nd and 3rd pairs of legs loam-coloured with a blue reflection, tibiae steel-blue at the base with a dense tuft of brownish bronze hair-scales, mixed with white in the middle, and the tibiae bordered with golden yellow on the hindlegs. Tarsi of the 2nd pair steel-blue at the base, densely covered with compressed long brownish bronze hair-scales, white at the base, tarsi of the hindlegs with similar hair-scales, but golden yellow at the base. The scaled parts of the wings beneath golden bronze. 15 mm. Villa-nova.

T. marcia Drc. Forewing black, a spot at the cell-end and a central streak extending to the base hyaline. Hindwing hyaline, distal margin and veins black. Head, thorax and abdomen black. Anal tuft yellow. Abdomen above with metallic golden bands, beneath black. Collar yellow. Antennae black. Legs black, with yellow bands. 15 mm. Mexico, Dos Arroyos, Guerrero, 350 m. September.

26. Genus: **Neosphecia** Le Cerf.

Head round, antennae of medium length, gradually thickened, straight. Palpi rather long, the 3rd joint small and pointed. Proboscis completely absent. Body strong, conical-cylindrical, anal brush short. Strong

legs of medium size, hind tibiae bent somewhat S-shaped. Forewing with a well developed vein 1, not divided at the base, 2 before the interior angle of the cell, 3 from this angle and nearer to 4 than to 2, 7 and 8 not stalked, 9 from the anterior angle of the cell, 10 and 11 proceeding almost from the same place of the cell. Hindwing: 1a short, 2 and 3 near the interior angle of the cell, 4 from the cell, 5 from the anterior angle, 6 well developed, 7 absent. Type: *N. combusta* Le Cerf.

combusta. **N. combusta** Le Cerf (179 a). Head black. Palpi black on the 1st joint outside, yellow inside, the 2nd joint yellow above, reddish yellow and black beneath, the 3rd black at the base, yellow above. Antennae brown below, pale red above. Collar and thorax blackish brown, posterior part of the thorax as well as the metathorax with pale yellow hair. Abdomen blackish brown, the posterior margin of the 2nd segment and the anterior margin of the 3rd form a pale yellow band. Ventrums and anal brush unicoloured blackish brown. Legs blackish brown with some yellow marking. Forewing light rust-brown warming into yellowish, base black, distal area lighter, and a short hyaline streak at the base near the inner margin. Hindwing transparent, veins and margins reddish brown, fringes of all the wings blackish brown. 30 mm. Bolivia, Cochabamba. Only ♂♂ known so far.

27. Genus: **Premelittia** Le Cerf.

Head small, but projecting. Proboscis quite absent. Palpi medium-sized. Antennae fusiform. Body strong and rather long. Anal tuft very short. Legs long and strong, the hind tibiae with a short hair brush below before the middle and at the end. Forewing: vein 1 well developed, 2 before the interior angle of the cell, 3 from the angle and nearer to 4 than to 2, a joint short stalk of 7 and 8, 9 from the same place of the anterior angle of the cell, 10 and 11 on a very short stalk at the base, arising at 9. Hindwing: 1a short, 2 from the middle of the interior margin of the cell, and 3 before the angle of the cell, 4 and 5 from the angle, 6 well developed from the upper cell-angle, 7 close beside, 8 short. Type: *P. rufescens* Le Cerf.

rufescens. **P. rufescens** Le Cerf (179 a). Head pale yellow, palpi yellow. Antennae dingy yellow, the last third beneath brownish red. Collar pale yellow. Thorax chestnut brown with yellow-edged tegulae. Abdomen brown, the 2nd segment behind with a yellow band, the 1st, 3rd and 5th broadly spotted yellow laterally, these spots narrowing down and forming rings on the segments, ventrums quite yellow. Legs yellow, tarsi darker. Forewing with a broad brown costa and discal mark, the distal margin likewise very broadly brown, so that the hyaline areas are rather small. Hindwing transparent, margins and veins brown. Fringes of all the wings greyish brown, lighter at the abdominal margin. 35 mm. Bolivia, Cochabamba. 1 ♀ known.

28. Genus: **Melittina** Le Cerf.

Head rather broad, palpi short, the 1st joint with long hair beneath. Proboscis well developed. Antennae short with thick clubs. Body short and thick without a projecting anal brush. Broad, rounded wings; forewing: vein 1 rudimentary, not divided at the base, 2 before the interior angle of the cell, 3 from that angle, 7 and 8 stalked as far as half their length, 9 from the anterior angle of the cell, 10 nearing 9 at the base, 11 more remote from 10. Hindwing: 1a very short, 2 near the middle of the interior margin of the cell, 3 before the angle, 4 from this angle bent towards the middle, 5 from the discocellular angle, 6 from the upper cell-angle, and 7 from the same place. Type: *M. nigra* Le Cerf.

nigra. **M. nigra** Le Cerf (179 b). Head blackish blue. Palpi black, slightly mixed with whitish, the 1st joint provided with a very long hair-tuft. Antennae blackish blue, pale yellow outside, club reddish beneath. Collar, thorax and abdomen blackish blue. Legs blackish blue with white or pale yellow markings. Forewing transparent, but dusted sooty, so that the costa and discal vein are not very prominent, veins and margins darker. Hindwing likewise sooty transparent. Fringes of all the wings rather broad, blackish grey. 21.5 mm. Brazil. 1 ♀.

29. Genus: **Melittia** Hbn.

Antennae growing thicker at the ends, finely dentate in the ♂, a few small bristles at the extreme apex. Tongue normal. Tibiae and tarsi provided with mostly long tufted hair, except the last 2 or 3 tarsal joints. Forewing: veins 7 and 8 stalked, otherwise similar to *Paranthrene*. Hindwing: vein 5 arises in the centre of the cross-vein, 6 and 7 on a long stalk. Type: *M. cucurbitae* Harr.

cucurbitae. **M. cucurbitae** Harr. (= satyriniformis Wkr., tibialis Drury) (179 b). Head metallic green, face whitish. Palpi pale orange, whitish at the bottom. Antennae blackish green. Thorax metallic olive green, sometimes warming into brownish olive. Legs orange, tarsi black with white rings. Hind tibiae inside with long black hair, outside with long orange hair. Abdomen above reddish orange with narrowly green-edged segments, a series of black dots on the dorsum; the 1st and 2nd segments olive green like the thorax, abdomen beneath lighter orange. Forewing dark metallic olive green with brownish darker fringes, a short hyaline streak at the base; under surface similar, though sometimes darker in the total colour. Hindwing transparent with a beautiful bluish reflection, veins and margin greenish, fringe brownish. ♂: 22—26 mm. ♀: 28—35 mm. Canada, United States. New Mexico. The imago appears in the north from June till August, in the south in April and May,

and again in July and August, thus two breeds here. The eggs are deposited on all parts of melon-pumpkins and allied plants, but chiefly on the stems and leaf-stalks. For its pupation, the larva known as "pumpkin-borer" leaves the stem and spins a rather solid cocoon near the soil between stalks or even a few centimetres in the soil itself. — ab. *amoena* Hy. Edw. A not quite clear aberration which is only mentioned here for the *amoena*. sake of completeness. Forewing without the hyaline streak, abdomen black with a purple reflection, the segments laterally greenish white, anal tuft orange brown with black and white hairs, the tarsi black. Kansas. — var. *ceto* Ww. (179 b). The marginal line of the hindwing narrower, about as broad as vein 2 at the apex, *ceto*. the space between 6 and 7 transparent in the ♂. 29—37 mm. Especially in the States of the Atlantic Coast.

M. snowii Hy. Edw. (179 b) is very near to *cucurbitae*, but the parts being olive green in the latter. *snowii*. such as the wings, thorax etc., are more greyish brown in *snowii*, without any metallic reflection. The abdomen is paler orange, light grey beneath. Forelegs whitish, mixed with light brownish hair, femora white. Middle legs greyish brown, hindlegs whitish outside, femora orange, black inside. 25 mm. Kansas. Apparently only 1 ♂ is known.

M. satyriniformis Hbn. (179 b). Head blackish bronze, white before the eyes. Palpi: 1st joint black, *satyriniformis*. 2nd red outside, 3rd red with a black apex. Antennae black. Collar, thorax and abdomen blackish bronze, 7th segment greyer. Anal tuft black, laterally white. Ventrally, the two first segments are black, the following ones scarlet in the middle, edged with black. Legs chiefly black with some white and red. Hind tibiae with projecting black hair, intermixed with scarlet outwardly, with whitish blue hair in the centre of the tibiae, more prominently white beneath, the tarsi black and red, scantily haired. Forewing black with a greenish blue reflection, a short hyaline streak at the base. Hindwing transparent, lustrous blue, veins and margins black, a few whitish blue scales at the base, fringes of all the wings blackish bronze. 31 mm. Colombia, but presumably in the whole north of South and Central America, where there are suitable habitats.

M. pulchripes Wkr. (179 b). Dingy golden green. Head behind and around the eyes white. Palpi white. *pulchripes*. Thorax with whitish hair behind on each side. Abdomen above pale red, the 5 last segments with an almost square black spot, dingy yellow beneath. Legs black with white bands, tibiae with red hair outside. Forewing dingy golden green, hindwing transparent. 29—38 mm. Honduras, Venezuela, Colombia, Parà. — The close affinities between *M. satyriniformis*, *cucurbitae* and *pulchripes* and their distinctions have been largely dealt with by LE CERF in OBERTHÜR, Lep. comp. 14, p. 150—160.

M. gloriosa Hy. Edw. (179 c). Head grey, face white. Palpi white outside, yellowish above. Collar *gloriosa*. and thorax greyish brown. Antennae dark ochreous, with darker dents. The 1st, 2nd and 4th abdominal segments above greyish brown, laterally orange, the two last segments and the anal tuft blackish with a feeble blue metallic reflection which is also slightly indicated by a few scales on the posterior margins of the segments, under surface whitish. Anterior and middle femora and tarsi brownish, here and there mixed with little orange. Hindlegs with long orange hair inside, outside black with straw-coloured admixtures, especially towards the base. Forewing greyish brown, warming into olive or orange, beneath with more orange. Hindwing transparent, veins and inner margin orange, fringe greyish brown. The ♀ has the hindwings thickly dusted with orange above and beneath with brown fringes. ♂: 40—45 mm. ♀: 40—58 mm. South California, Arizona. — Larva in the roots of the sumac (*Rhus laurina*) and the roots and stalks of *Megarrhiza*.

M. grandis Streck. (= *beckeri* Drc.) (179 c). Head and thorax greyish brown, palpi yellow. Legs yellow, *grandis*. tarsi with black rings; hindlegs inside with long orange hair, blackish in the middle on the top. Abdomen brown, sides orange, lighter orange beneath. Forewing beautifully olive green with a brown streak, yellowish beneath except the apex which remains greenish. Hindwing transparent in both sexes, veins dingy orange, fringe greenish brown, the partition-line darker. Very similar to *gloriosa*, but immediately discernible by the colour of the abdomen, of the forewings and above all by the hindwings being invariably transparent in both sexes. ♂ 38 mm, ♀ 50 mm. Arizona, Texas, Mexico.

M. lindseyi Barn. & Rothsch. (= *superba* Barn. & Linds., *barnesi dalla Torre*). A very large species. *lindseyi*. Head and thorax dull greenish grey. Collar and ends of the patagia with traces of yellow hair. Palpi yellow, antennae black. Abdomen beneath yellowish white with black traces on the posterior margins of the segments, above the two first segments and the 4th yellow with black posterior margins, the 3rd, 5th and 6th white, likewise with black posterior margins, the rest bluish black. Forelegs yellow, tibiae and tarsi marked black, middle legs yellow, femora blackish on one side, tibiae apically black and laterally reddish orange, tarsi black with some yellow at the base of the segments; posterior femora black, beneath in the distal half orange and yellow towards the end, posterior tibiae reddish orange, outside black, mixed with yellow and whitish. The bluish black parts have a beautiful metallic reflection. Forewing dull greyish green with a yellowish shine near the base, fringe lighter and darker ochreous, dingy yellow in the basal half. Hindwing transparent, with

reddish orange hair at the base and in the anal region, veins orange with black scales, a black marginal line and ochreous fringe. ♂ 51—57 mm, ♀ 63—65 mm. Kansas, Arizona.

magnifica. **M. magnifica** Beut. (179 c). Head bluish black, palpi orange, apically black. Thorax steel-blue, slightly orange laterally. Antennae bluish black, brownish red towards the apex beneath. Abdomen above and beneath metallic steel-blue, legs steel-blue (hindlegs absent, they were surely also steel-blue, inside perhaps orange). Forewing steel-blue, inner margin broadly light orange, narrowing towards the interior angle, fringe light orange. Hindwing deep bright orange above and beneath, forewing beneath orange, the anterior quarter blackish. ♀ 42 mm. Of this extremely beautiful species only one female specimen has become known so far. Austin, Texas.

dolens. **M. dolens** Drc. Head, thorax, tegulae, abdomen and legs black (antennae absent). The 4th abdominal segment broadly yellow, anal tuft black. Forewing black. Hindwing hyaline, veins and fringe black. 32 mm. Brazil.

hervei. **M. hervei** Le Cerf (179 d). A large species easily discernible especially by the shining dark yellow tarsi of the hindlegs. Head blackish blue, white before the eyes. Palpi whitish yellow. Collar and thorax blackish blue. Abdomen quite black. Legs black, tibiae of the hindlegs long-haired, the tarsi still longer and beautifully ochreous dark yellow. Forewing black with two hyaline spots; one in the centre of the wedge-area, one in the lower part of the distal area, shortly before the anal angle. Hindwing transparent, with a blue reflection, the veins and the rather broad margins black. Anal angle with shining dark blue scales. 39 mm. Peru, Chanchamayo.

arcangelii. **M. arcangelii** Giac. (180 h). Body, antennae and palpi above black, ochreous beneath. Collar and the anterior margin of the thorax yellow, at the end of the thorax reddish ochreous hair extending beyond the first abdominal segments. Forewing golden yellow above, the costal and distal margins black like the fringe, $\frac{1}{3}$ of the forewing below the costal vein black or blackish grey, a narrow hyaline streak below it, veins black. Hindwing basad as far as about half vermilion, the rest hyaline, veins reddish, fringe black. Anterior and middle legs absent, hindlegs inside with tufted black hair, tibiae outside white, the tarsi inwardly with four small black hair-tufts. 35 mm. Argentina. — Our figure is copied from a water-colour painting which the author, Mr. GIACOMELLI from la Rioja, had the kindness to send to us.

bergii. **M. bergii** Hy. Edw. Palpi and anterior tarsi dark orange. Antennae, femora, tibiae and posterior tarsi bluish black. Thorax and abdomen dull black with a metallic lustre. Forewing dull orange, costa blackish; the black colour widens towards the cell, decreasing again towards the apex. Hindwing orange, transparent along the costa. 37 mm. Buenos Aires.

superba. **M. superba** Rothsch. (179 c). Head blackish brown, palpi brown. Collar with a dull blue reflection, thorax metallic silvery, opalescent reddish yellow, the centre metallic blue. Antennae black. The two first abdominal segments metallic dull blue, the following ones deeper steel-blue, the two last metallic bronze green. Thorax beneath opalescent silvery white, abdomen beneath white, opalescent yellowish. Forelegs black, tarsi yellow, middle legs metallic blue, tarsi sometimes silvery, hindlegs with dense long hair, tibiae above and inside broadly yellow, below and outside black, mixed with metallic blue-reflecting hair-tufts, tarsi black, partly with grey hair. Forewing above and beneath of a brilliant metallic blue, costa and the broad distal margin dull black. Hindwing obliquely divided, from the base to the distal margin about $\frac{3}{5}$ metallic blue, the last two fifths transparent, fringe black, abdominal margin bluish. 44 mm. Eastern Peru, Marcapate, 1100 m.

imperator. **M. imperator** Rothsch. (179 d). ♀: forelegs black, tarsi scarlet; middle legs blackish brown, tarsi scarlet, hindlegs very densely haired scarlet, with hair-tufts on the tibiae and tarsi. Palpi and head blackish brown, face with two white streaks. Thorax blackish brown with reddish spots. Abdomen purple, anterior margins of the segments scarlet. Forewing metallic bluish green. Hindwing hyaline, veins, margins and apical third metallic bluish green. 45 mm. Obidos, Amazons. April.

pomponia. **M. pomponia** Le Cerf. One of the smallest species of the genus (only 17 mm). All the wings transparent, veins and margins bronze black, distal margin of the discocellular vein yellowish which colour expands as far as the apex at the margin, fringe short, bronze black. Head thick, black, a few white hairs around the eyes and at the collar. Antennae bronze black. Eyes rather large, orange. Palpi black, the 2nd and 3rd joints inside and outside white. Collar, thorax and abdomen bronze black, a very fine ring of white scales on the 2nd segment beneath, on the 6th above. Anal tuft short and pointed, black. Forelegs blackish blue, white at the base. Hindlegs: femora black, with a white line below, tibiae bronze black with long hair of the same colour, towards the end a thick fan-like tuft of orange hair, tarsi bronze black. Peru, Payta.

smithi. **M. smithi** Drc. Forewing black with a narrow hyaline streak from the base to the end of the cell, an oval hyaline spot below it, fringe greyish. Hindwing hyaline, veins and fringe black, the bases of all the wings covered with long yellow hair. Head, thorax and abdomen brownish black, each segment margined with yellow, the under surface of the thorax and abdomen yellowish brown. Antennae black. Legs yellow, except the

hindlegs which are thickly covered with black hair; a few yellow hairs near the body. 32 mm. Mexico: Rio Papagaio, Guerrero, 400 m; Dos Arrayos, Guerrero, 350 m. September, October.

M. butleri *Drc.* (179 d). Forewing hyaline, apex and costal margin black. Hindwing hyaline, margins *butleri*. black. Antennae black. Thorax and abdomen beautifully yellowish brown, abdomen more black, though the posterior segmental margins always remain yellowish brown. Ventrums and apex of abdomen beneath yellowish brown. 30—33 mm. Mexico, Oaxaca.

M. cyaneifera *Wkr.* (179 d). Black. Palpi scaled black. Antennae rust-coloured apically. Thorax and abdomen brownish, scaled felt-like, dingy yellow beneath. Forelegs the same; hindlegs thickly covered with black hair which are inside reddish, the joints with white hair. Wings transparent, fringes purple, margins of the forewing, transverse band and distal area purple black, anal region of hindwing more or less metallic bluish green. 35 mm. Brazil, Rio de Janeiro. — var. *reducta* *Le Cerf* has only three veins in the distal area, while *reducta*. the type has four; it is said to appear especially in the north of the range.

M. umbrosa *sp. n.* (179 d) is a strange species which at first sight reminds us of the Asiatic *M. eurythion umbrosa*. *Ww.* (Vol. X, pl. 95 f). But it lacks above all the light under surface of the abdomen, otherwise it does not differ very much from that likewise very variable species occurring in India, Indo-China and farther. The ♂ is bluish black above and beneath (antennae absent). Palpi white with a few black hairs. The last hairs of the anal tuft are dull grey. Wings transparent, margins and veins normal, black; a greyish white tinge in the apical area on the broad distal margin, as in *eurythion*. The distal area is crossed by five veins, the uppermost of which bifurcates shortly before it enters the margin; fringe dull greyish black. Legs black, tarsi and tibiae of the hindlegs thickly covered with black hair, above with two dingy yellow hair-tufts; tarsi of the forelegs white, of the middle legs black with white rings. 1 ♂. 26 mm. Brazil, Nova Teutonia, Sa. Catharina. Type in the Coll. PLAUMANN.

M. latimargo *Btlr.* (179 e). Wings hyaline, veins black; forewing: costa, discal streak, a broad apical margin and inner margin blackish brown, fringe pale brown; hindwing with thin blackish brown margins, fringe pale brown, inner margin as far as the base covered with a few green scales. Body above loam-coloured, more ochreous towards the head. Antennae black above, rust-coloured below. Chest and the first pair of legs ochreous, the second pair brown, ochreous inside, femora of the hindlegs scaled, tibiae and tarsi with long recurved brown scales, with a few interspersed reddish hair-scales, tibiae below with a pale green spot and two cream-coloured and blackish brown terminal tufts. 40 mm. Brazil, Curitiba, Paraná. — It is closely allied to *cyaneifera*; *latimargo* is mostly larger, more yellow, with different legs, broader discal streaks and margins, no blue in the hindwing.

M. rugia *Drc.* Head, antennae, tegulae, thorax and abdomen black. Palpi white, black apically. Legs *rugia*. black with black hair, bright red at the end of the joints. Forewing bluish black, cell hyaline, fringe black; hindwing hyaline, veins and fringe black, the inner margin from the base to the anal angle thickly covered with metallic bluish green scales. 42 mm. Peru, Chanchamayo. 350—500 m.

M. lagopus *Bsd.* Antennae black, dentate in the ♂. Palpi and chest white. The collar exhibits a few *lagopus*. white hairs. Thorax brown. Legs brown, curled white at the joints, the hindlegs black-haired. Abdomen black, somewhat shining, the 2nd segment margined with white. Anal tuft black. Forewing black with a transparent longitudinal streak extending beyond the middle, cut into two parts by a vein, and a transparent distal area divided into four parts by three veins. Hindwing transparent, veins, fringe and a small bow below the costa black. 26 mm. Cayenne, on the Oyapock River.

M. brabanti *Le Cerf* (179 e). Head blackish grey, white before the eyes. Palpi yellowish, mixed with black. Antennae strong and long, black above, brown beneath. Collar and thorax olive grey, thoracic sides dingy yellow. Abdomen greyish black, a slight white transverse stripe on the 2nd segment. Anal tuft rather long, tripartite, blackish grey, ventrum dingy yellow. Legs greyish black and yellow, the coxae all yellow, hind tibiae with long black hair which are intermixed with whitish yellow above, the tarsi likewise with blackish hair as far as the end, more scantily whitish yellow above. Forewing transparent, margins, veins and discal vein bronze black; hindwing transparent, margins and veins bronze black, bluish green scales at the abdominal margin; fringes of all the wings bronze black. 44 mm. French Guiana, Gourdonville. 1 ♂.

M. xanthopus *Le Cerf* (179 e). Head blackish olive, face greyish yellow, the eyes narrowly margined with white. Palpi outside yellow, white inside. Antennae long and thick, not bent before the tips, black above, brown beneath. Collar and thorax olive brown. Abdomen blackish, the posterior margin of each segment finely margined with yellow, anal tuft light olive brown. Ventrums light olive, the last joints and the anal tuft yellow. Legs dingy yellow and olive brown, posterior tibiae with long black hair, mixed with yellow at the base and below, darker yellow above and outside. Tarsi densely covered with long black hair, the last two joints less long and bright yellow. Forewing transparent, veins, margins and discal vein, all not very broad, sooty black.

Hindwing transparent, veins and margins black, anal angle blackish with a blue reflection; fringes of all the wings blackish brown. 34—44 mm. Peru, Vilcanota, 3000 m. Bolivia, La Paz.

sulphureopyga. **M. sulphureopyga** *Le Cerf* (179 e). Head black, face brown, eyes margined with white. The 1st joint of the palpi white, the 2nd yellowish white, black in front, the 3rd black. Antennae long, black, brown beneath in the last third. Collar and thorax olive brown. Abdomen likewise olive brown, the 7th segment sulphur-coloured, anal tuft again olive brown. Ventrums sulphur-coloured, slightly covered with brownish bronze scales at the base, turning more and more yellow towards the apex. Legs black and brownish, the hind tibiae densely covered with long sulphur-coloured hair, just as densely blackish brown at the end with a bluish reflection, tarsi on the two first joints densely covered with blackish brown hair, the three last slightly black, lighter above. Forewing transparent, costa, margins, disc and veins dull black, distal margin blackish brown, not very broad, somewhat oblique, powdered with a few light scales; hindwing transparent, veins and margins black, anal region with a few blackish brown scales. 37—41 mm. Panama, on the Volcano of Chiriqui (Costa Rica), in May until July.

powelli. **M. powelli** *Le Cerf* (179 f) is one of the largest species; at first sight it is somewhat similar to *xanthopus* or *sulphureopyga*. Antennae black, brown beneath, slightly bent before the tips. Collar and thorax olive grey, with some yellow hair behind. Abdomen black, each segment finely margined with yellow, the last quite light yellow, anal tuft olive, laterally yellow. Abdomen, thorax and coxae quite light yellow beneath. Forelegs and middle legs chiefly yellowish with little black, hind tibiae and tarsi long and densely black-haired, somewhat yellow outside. Forewing transparent, the margins and disc more intensely than in *xanthopus*, the distal margin broader, all bronze black; hindwing transparent with a blue reflection, veins and margins blackish brown, anal angle with a few steel-blue scales. Fringes of all the wings long and blackish bronze. 51 mm. Peru, Chanchamayo. 1 ♀.

funesta. **M. funesta** *Le Cerf* (179 f). Head blackish blue, white before the eyes, palpi black, white outside and in front. Collar purple black. Thorax quite blackish blue, abdomen, sides of the 1st and 3rd segments yellowish white. Ventrums blackish blue, dusted light. Legs blackish blue and yellowish white, hind tibiae blackish blue, with a bronze reflection, with dingy light yellow hair in front and behind, the tarsi again black-haired. Forewing purple black, with a bronze reflection, and three hyaline spots: a longer basal streak, a very small one behind it, then a short one before the anal angle, which is usually divided by a vein. Hindwing transparent with a blue reflection, veins and margins purple black. 31 mm. Brazil.

chimana. **M. chimana** *Le Cerf* (179 f). Head blackish blue, white before the eyes. Palpi blackish brown, mixed with whitish on their whole surface. Antennae black. Collar and metathorax white. Abdomen black, the whole 1st segment and the sides of the 2nd white, single white scales covering yet the two last segments. Ventrums yellowish white, anal tuft small. Legs black and white, the hind tibiae with black projecting hair, interrupted by white outside and above at the ends, tarsi likewise black-haired, though less intensely, somewhat white at the base. Forewing brownish black strewn with pale blue scales, a short hyaline streak at the base; hindwing transparent, veins and margins black. Fringes of all the wings greyish bronze. 32 mm. Ecuador, La Chima.

josepha. **M. josepha** *Le Cerf* (179 f). Head greyish bronze, extensively white before the eyes. Palpi yellowish white, black outside at the apices. Antennae black, the apex below brownish red. Collar blackish blue. Thorax blackish blue, yellow at the base of the tegulae, metathorax with black and yellow hair. Abdomen blackish bronze, bearing two yellow spots on each segment above, the last segment with a yellow central spot, ventrums whitish. A short dark anal brush. Legs black and yellow, the tarsi of the hindlegs just as long as the tibiae, both covered with long black hair with two white intermixtures at the base of the tibiae, with especially brilliant white spurs beneath. Forewing transparent, margins, the broad costa and the distal margin blackish brown, warming into yellowish inwardly. Hindwing transparent, veins and margins blackish. Fringes of all the wings greyish bronze. 36 mm. Ecuador, Zaruma. Described according to 1 ♀.

louisa. **M. louisa** *Le Cerf* (179 g). Head black, face brown, white before the eyes. Palpi yellow warming into reddish. Antennae black above, brown beneath. Collar pale orange, black behind it. Thorax black, shoulder-spots and metathorax pale orange, thorax beneath lighter yellow. Abdomen black, the 3rd segment completely ochreous orange, the centre of the 4th, the sides of the 5th, 6th and 7th ochreous orange. Anal tuft short, orange. Ventrums yellowish grey. Legs yellow and black, hair-tufts of the hindlegs inwardly mostly black, two broad ochreous orange tufts projecting on the tibiae, whitish grey inside. Forewing transparent, costal margin, the very broad oblique distal margin and the veins black, distal area crossed by three veins; hindwing transparent, veins and margins black, the narrow anal angle half black, half ochreous. Fringes of all the wings greyish bronze. 34.5 mm. Mexico.

oberthuri. **M. oberthuri** *Le Cerf* (179 g). Head broad, reddish yellow. Palpi short, not reaching the base of the antennae, pale yellow. Antennae rusty brown, lighter beneath, basal joint white. Collar and thorax reddish yellow. Abdomen somewhat lighter on segments 1, 3 and 5; 2, 4 and 6, however, darker, almost rusty brown,

the 7th and the anal brush of the same colour, ventrum light yellow. Legs chiefly yellow, but lighter than the body, the tibiae and the tarsi of the hindlegs with thick and long hair-tufts varying between a lighter chrome-yellow, brown and blackish. Forewing transparent with a yellow spot at the base, the broad costa and the likewise broad, obliquely cut off distal margin as well as the veins brownish black, the distal area with four veins. Hindwing transparent, veins and margin bronze brown. Fringes of all the wings greyish bronze. 41 mm. Amazons, Iquitos. Owing to the beautifully haired legs, the size and the shining body, the insect numbers among the most beautiful species of *Melittia*.

M. pauper *Le Cerf* (180 a). Head greyish brown, white before the eyes. Palpi white at the base beneath, *pauper*, yellowish outside and above, with a few brown scales in the middle of the 2nd joint (antennae absent). Collar and thorax greyish olive, beneath with a white spot on each side. Abdomen greyish olive, all the segments finely margined with whitish, ventrum dingy yellow. Anal tuft small, yellowish. Legs yellowish white warming into olive grey. Hind tibiae and tarsi rather long, with yellowish grey hair. Forewing transparent, costal and distal margins as well as the discal mark rather broadly olive grey, a sharp longer dent of the same colour extends from the discal vein inwardly into the hyaline area. Hindwing transparent, veins and the narrow margin olive grey. Fringes of all the wings dull grey. 32 mm. Peru, Lima. March.

M. riograndensis *Brèth.* has been described in: *Anales de la sociedad rural argentina* 54 (1920), to which *riograndensis*. there was no access.

(29a.) Genus: **Leuthneria** *dalla-Torre*.

L. ruficincta *Fldr.*, named and figured as *Eublepharis Fldr.* in: *Reise der Novara Zool.* 4, pl. 75, fig. 4 *ruficincta*. (1874), described in *SEITZ Vol. 14 (Africa)*, p. 531 as *Melittia* (Sudan); the statement "South America" in *JUNK's Cat. 31 Aegeriidae* remains unintelligible. It has thus been twice introduced, once as *Melittia* and once as *Leuthneria* for Africa and for America. The unique insect does not make the impression of a *Melittia* in *FELDER's* work, for which reason *DALLA-TORRE* proposed a new description of *Leuthneria*; there exist, however, neither descriptions for *Eublepharis*, nor for *Leuthneria*.

30. Genus: **Callithia** *Le Cerf*.

Antennae of medium length, thin at the base, thickened before the end. Palpi rising, small and pointed. Proboscis well developed. Thorax convex, abdomen delicate and rather short with a small anal brush. Feet long, especially the posterior ones, their tibiae with dense and long hair in the last quarter, which decoration is also continued on the tarsi. Forewing: vein 1 fine, not divided at the base, 2 and 3 arise before the interior angle of the cell, separated at the base, 4 from the interior angle of the cell, 7, 8 and 9 stalked, proceeding from the anterior angle of the cell, 10 and 11 separated at the base and then nearing each other. Hindwing: 1 a short, 2 and 3 before the interior angle of the cell, 4 from the angle, 6 absent, 8 confluent with the costal vein, no anal lobe. Type: *C. oberthüri* *Le Cerf*.

C. oberthüri *Le Cerf* (180 a). Head blackish bronze, white behind, a few white scales below the base *oberthüri*, of the antennae. Palpi erect, black, white in front. Antennae black, the apex above and the club beneath brownish red. Collar brownish bronze. Thorax shining black, metathorax the same with two yellow lateral spots. Abdomen dark chocolate brown, the margins of the segments black, the two last quite black, the anal brush almost black. Metathorax beneath yellowish, the two first segments black, the following ones yellow. The posterior margins of the 1st and 3rd segments above very finely light yellow. Forelegs black, reddish beneath, femora and tibiae of the middle legs black with little yellow. Hind femora black, white beneath, a few white hair-scales above at the beginning, a light yellow spot outside, almost in the middle. After this the *Melittia*-like hair begin, passing over to the tarsi the last joints of which, however, are hairless. Forewing deep chocolate brown, hindwing transparent, opalescent blue, margins and veins chocolate brown. 34 mm. Cundinamarca, Colombia. *LE CERF*, in 1900, had only 1 ♂ at hand for examining this species; later on, *FASSL* brought a larger number from Muzo (Colombia), but unfortunately also only ♂♂, all of which exhibit somewhat less distinct yellowish white markings than the ♂ of *LE CERF*.

31. Genus: **Calasesia** *Beut.*

Palpi erect with appressed scales, extending to the height of the head, 3rd joint long and narrow. Antennae gradually thickening towards the apex, then short and pointed towards the end. Legs scaled, hindlegs with small hair-tufts on the spurs of the tibiae, tarsi tuftless. Abdomen tapering, anal tuft small. Forewing remarkably round at the apex, with 10 veins: 3—6 from the cell, 7 and 8 grown together, 10 from the base. Hindwing: vein 2 from the cell, 4 and 5 from the end of the cell, 6 from the middle, 7 and 8 absent. Type: *C. coccinea* *Beut.*

C. coccinea *Beut.* (180 b). Head black. Palpi yellow, black in front. Collar whitish in front. Thorax *coccinea*, and abdomen blackish bronze with a metallic reflection. Antennae brownish black. Thorax beneath with

scarlet spots on each side. Legs metallic brownish black. Forewing intensely scarlet, the distal margin and a round spot behind the cell-end blackish brown, the hindwing brown. Forewing beneath orange, brown outside. Hindwing beneath brown. 12 mm. New Mexico. 1 ♀.

32. Genus: **Paranthrene** Hbn. (*Memythrus* Newm.)

Palpi erect, the 1st and 2nd joints very long with thick hair, the 3rd joint short with appressed scales. Antennae more or less dentate with ciliary tufts. Abdomen of ♂ with a plain anal tuft or four long pencils at the end of the last segment. Proboscis present. Forewing with 12 veins, 7 and 8 stalked. Hindwing with 4 and 5 from the end of the cell, 6 from the cell, 7 and 8 very long. Legs long, tibiae feebly haired. Type: *P. tabaniformis* Rott. from Europe.

tricinctus. **P. tricinctus** Harr. (180 a). Head black, collar yellow. Palpi black, yellow towards the apex. Antennae bluish black above, red beneath. Thorax black with a yellow shoulder-spot and lateral stripe. Abdomen black with a blue reflection: ♂: segments 2, 4 and the two last, ♀: 2, 4, 6 above and beneath yellow. Anal tuft black. Legs black, middle and hind tibiae partly orange, the posterior ones also yellow, tarsi orange. Forewing violettish black with a short hyaline streak at the base, inner margin and costa reddish near the base, these parts being yellowish beneath. Hindwing transparent, veins, discal mark and margins violettish black, reddish orange beneath. 25—28 mm. Canada, New England and Central States, to the west as far as Ohio and Michigan. — Larva in twigs and trunks of poplars and willows, also in the galls of *Saperda concolor*, two larvae often behind each other. For the pupation the passage is closed with a silky spun membrane which is pierced by the emerging imago. It hibernates in the passages, pupates in May, and emerges in June and July.

robiniae. **P. robiniae** Hy. Edw. (180 a). Head and palpi yellow. Collar black, yellow in front and behind. Antennae brownish orange. Thorax deep black with a yellow posterior margin and yellow sides. The three first abdominal segments above and beneath black, the 2nd and 3rd behind with a yellow ring, the remaining segments quite yellow. Legs yellow, femora mixed with black. Forewing orange brown with darker veins, yellowish beneath. Hindwing transparent with a narrow margin and orange brown veins. 26—36 mm. Nevada, California, Washington. — The larva is said to live, like that of *tricinctus*, in *Populus alba*, *canescens*, and *Robinia pseudoacacia*. The insects appear in the Pacific States in March and April, in Nevada in July.

cupressi. **P. cupressi** Hy. Edw. (180 a). ♂: head, palpi, antennae orange, face lighter. Collar purple brown, orange in front, golden yellow behind. Thorax brown, laterally and behind margined with golden yellow, besides with small posterior yellow hair-tufts on each side, the 1st abdominal segment black, the 2nd deep orange, yellow behind, the 3rd yellow, orange behind, the others as well as the 4 anal appendages deep yellow. Legs orange, femora black and orange. Hind tibiae yellow and orange, tarsi orange. Forewing purple brown, yellowish at the base with an orange streak along the middle, becoming indistinct at the discal vein. Hindwing transparent, veins purple brown, margins and fringe violettish brown with an orange line at the inner margin towards the base. Beneath all the colours are more intense. ♀: similar to the ♂, but without the 4 small anal brushes. Forewing mostly paler, segments 2—5 broadly orange, the others yellow. Collar orange, broadly yellow behind, palpi yellow, orange at the bottom. 30—35 mm. Utah, Colorado, Arizona.

polistiformis. **P. polistiformis** Harr. (180 b). Head reddish, face whitish. Palpi reddish. Antennae above black, red beneath. Thorax brown, sometimes laterally reddish. Abdomen brown, warming into violet, the 2nd and 4th segments with a yellow ring, the anal segment with 4 orange brown small brushes, the exterior ones being shorter. Legs orange, femora black. Forewing brownish black with a violet shine and a short hyaline streak at the base; beneath orange at the base. Hindwing yellowish transparent with violettish brown margins, discal vein oblique, inner margin orange at the base. The ♀ is stronger and dark on the whole, without anal appendages. 21—37 mm. Vermont, New York, New Jersey, North Carolina, South Carolina, Kentucky, Illinois, Missouri, Michigan, Ohio, Minnesota. — Larva in cultivated and wild grape-fruits, especially in the Southern States; it may do much harm and is known as "orange-borer".

scepsiformis. **P. scepsiformis** Hy. Edw. (180 b). Head purple brown, palpi and collar rusty brown. Antennae black, dingy orange beneath and at the apex. Thorax dark brown, sometimes margined with yellow. Abdomen blackish, the 2nd segment yellow behind. Legs black, tibiae and tarsi marked orange. Forewing from dark brown to blackish with a bluish reflection, somewhat rust-coloured at the inner margin, the base now and then yellow. Hindwing transparent with a broad distal margin occupying almost one third of the wing. Margins and fringe violettish black, base and inner margin rust-coloured, more orange beneath. 25—30 mm. Maryland, Kansas, Texas.

simulans. **P. simulans** Grt. (= *luggeri* Hy. Edw.) (179 g). Head black, orbita lemon-coloured. Palpi black at the bottom, otherwise yellow. Antennae black. Collar lemon-coloured. Thorax black, behind with yellow marks extending to the forewings. Anterior coxae yellow, femora black with some yellow, tibiae yellow and orange, tarsi orange. Abdomen black with a broad yellow band on the posterior margin of each segment; they may become so broad that the abdomen appears to be quite yellow. The short anal tuft is darker, more orange. Forewing thinly covered with dingy orange brown scales, with a strong blackish brown costal margin and a

less strong inner margin, discal mark feeble. A narrow hyaline streak at the base and a broad hyaline area at the distal margin. Under surface generally paler, but mixed with orange. Hindwing transparent, opalescent, margins narrow, brown. 27—35 mm. Rhode Island, New York, Pennsylvania, New Jersey, Illinois, Ohio, Minnesota. The larva lives for two years in the wood of red oak. — Imago flying from the end of May till July. — var. *luggeri* Hy. Edw. ♂ with a transparent area below the cell of the forewing. Abdomen black at the base, with a narrow yellow streak on the 2nd segment, the middle segments laterally yellow, anal tuft yellow. Anterior tibiae black above, middle and hind tibiae with small black spots. The total impression is thus darker.

P. palmii Hy. Edw. (179 g). Head black. Palpi orange, black at the bottom. Collar orange. Antennae pectinated, black, orange basally, ochreous apically. Thorax black, patagia, a broad spot behind and the shoulders at the forewings light orange. Abdomen dark orange with narrow anterior segmental margins. Legs dark orange, posterior femora partly black. Forewing purple brown, orange red at the base along the eosta almost to the centre of the wing, a hyaline streak between veins 1 and 2. Hindwing yellowish transparent, opalescent, veins, discal mark, the narrow margins violettish brown. 32—43 mm. Florida. — Larva presumably in oak (BEUTENMÜLLER).

P. asilipennis Bsd. (= *vespipenne* H.-Schäff, *denudatum* Harr., *bombyciformis* Wkr.) (180 b. e). ♂: head black, yellowish white beneath, reddish above. Antennae reddish, very long dentate. Collar dark orange brown. Thorax brown, patagia reddish, posterior part with a yellow transverse line. Abdomen dull brownish black with very narrow yellow posterior rings on each segment above and beneath. Legs orange, femora black. Forewing transparent with narrow brown margins and a reddish discal vein. Hindwing transparent with a very narrow brown margin. ♀: similar to ♂, but forewing deep brown, warming into violet, with an oblique red discal vein and a triangular hyaline area above the anal angle. Abdomen stronger, the 2nd segment above red. Antennae plain. 30—44 mm. From New Hampshire to Florida, to the west as far as Minnesota, and to the south as far as Texas. — Larva in the roots of ashes and alders.

P. dollii Neum. (180 c). Head black, orbita pale. Palpi, collar and antennae reddish. Thorax blackish brown, sometimes with reddish patagia. Abdomen black, the 4th and the following segments reddish behind, the 2nd and 4th with a yellow ring, rarely all the segments are provided with feeble yellow rings. Legs dull orange, femora black. Forewing brown with a violet reflection, orange at the base, dull orange brown beneath. Hindwing brown, transparent at the base and behind the cell, below the eosta. Sometimes the transparent areas are confluent above the discal vein. Altogether a very variable species. 28—40 mm. New York, New Jersey, Pennsylvania, Illinois. — var. *castaneus* Beut. (180 c) is like the type, but the thorax and abdomen are light chestnut instead of blackish brown. 30—40 mm. Kansas, Texas. — Larva in the wood of young poplars.

P. seminole Neum. (180 d). ♀: head and eyes light brown, palpi light brown with dark apices. Collar light brown with a red margin. Thorax brown with yellow patagia-lines and a yellow posterior margin. Abdomen light reddish brown, the segments margined with yellowish, the first three above narrowly black. Legs above brown, beneath yellow with reddish brown hair. Forewing chestnut brown with a yellow basal spot, a reddish streak along the middle and one at the inner margin, fringe brown. Hindwing transparent, opalescent, eosta, veins, discal vein and fringe reddish brown. Forewing beneath light chestnut or reddish brown with a yellow basal area. 40 mm. Florida. Described only according to a ♀, the ♂ being unknown.

P. admirandus Hy. Edw. (180 d). Head, the part between the eyes and palpi orange, orbita white, face pale yellow. Antennae reddish. Thorax dull brown, patagia yellow, with a broad light reddish spot at the base of the wings on each side, metathorax with a yellow transverse band. The 1st abdominal segment brownish black, the 2nd light yellow, the 3rd orange, the 4th yellow, the last three orange with yellow margins; beneath orange, the 3rd segment yellow. Anal tuft brown. Legs orange. Forewing dull brown with a violet reflection and a small yellow basal spot, orange beneath at the base. Hindwing transparent, veins and the not very narrow margins dull brown, from the margin a wedge of dark dusting between 3 and 4, somewhat orange at the inner margin. 30 mm. Apparently only 1 ♂ known. Texas.

P. fraxini Hy. Edw. (= *morrisonii* Hy. Edw.) (180 c). Head black. Antennae with a long yellowish preapical spot, quite yellow beneath. Palpi yellow at the base, black towards the apex. Thorax bronze purple black with a small tuft of white hair on each side. Abdomen bronze black like the divided anal tuft in the ♂. Legs black, tarsi dingy yellow, anterior coxae at the bottom yellow. Forewing purple black. Discal mark red, beneath at the base faded yellowish. Hindwing transparent, discal mark and distal margins purple black. 20 to 25 mm. Washington.

P. maculipes G. & R. Head bronze brown, palpi pale yellow. Thorax above and beneath bronze brown. Abdomen purple brown with a pale yellow ring on the 1st and 4th segments. Legs brown, marked dingy yellow. Forewing bronze brown with a few reddish scales. Hindwing bronze brown, fringe mostly lighter. 18—24 mm. Texas.

heucherae. **P. heucherae** Hy. Edw. (= *potentillae* Hy. Edw.) (180 d). Head brown. Palpi pale yellow with some black. Antennae dingy yellowish, the dentation black. Thorax brown with a few yellow scales. Abdomen dark, the 1st and 4th segments broadly bordered with yellow, the others slightly scaled yellow. Anal tuft black. Legs black with yellow bands. Forewing bronze brown, more or less dusted reddish. Hindwing bronze brown. Under surface on the whole more yellow. 20—24 mm. California, Texas.

palmiana. **P. palmiana** dalla-Torre (= *palmii* Neum.) (180 d). Head black. Palpi orange. Collar orange in front, yellow behind. Antennae reddish brown, dentation black. Thorax black strewn with reddish scales, beneath with a yellow spot on each side. Abdomen black, the 1st segment yellow, the four last segments with very broad yellow bands at the anterior margin, beneath with more orange bands, anal tuft also orange. Legs orange, femora black. Forewing black mixed with red scales. Hindwing black with reddish shadows, basal area transparent; under surface orange. The ♀♀ are mostly much larger and more robust. 15—27 mm. Arizona.

canscens. **P. canscens** Hy. Edw. (180 e). Head and palpi orange mixed with black and white hairs, appearing grey on the whole. Antennal shaft grey, dents brown. Thorax and abdomen black, thickly scaled grey above and beneath. Legs grey. Forewing brown, densely scaled grey, under surface brown, margins brown, fringe white. 18—24 mm. Kansas, Colorado.

mexicanus. **P. mexicanus** Beut. (180 f). Head black, palpi and collar white. Thorax black, patagia with white stripes. Abdomen black with a white band on the 2nd and the last 4 segments. Anal tuft black. Legs black with white bands. Forewing brownish black, white on the distal part between the veins. Hindwing black. 12 mm. New Mexico. — Apparently only ♂♂ are known.

fenestratus. **P. fenestratus** Barn. & Linds. Head, abdomen, legs and antennae black, the apical part of the antennae orange. Wings orange, fringes greyish brown, darker in the cell; costal margin as far as the end of the cell, base, inner margin near the base, radial and cubital lines blackish. Inner margin and the following vein of the hindwing black, the other veins with traces of black, near the base several transparent areas between the veins. 45 mm. Chiricahua Mts., Arizona. June.

33. Genus: **Bombosceles** Meyr.

Head smooth, eyes large, tongue present. Antennae pointed at the ends, about half ciliated in the ♂. Palpi short, bent upward, with appressed scales, compressed, pointed. Abdomen short, broadest in the middle. Anal tuft small. All the tibiae broadly covered with dense rough hair-scales, the middle and posterior tarsi with hair-tufts on three terminal joints. Forewing: vein 2 from the angle, 3 absent, 7 to the apex, 8 separated. 11 from $\frac{3}{4}$ of the length of the cell. Hindwing: 2 and 3 from $\frac{3}{4}$ of the length of the cell, 4 from the angle. 5 absent, 6 bent at the base and coalescent with 7.

cyanomyia. **B. cyanomyia** Meyr. (180 e). ♂: head, palpi, antennae, thorax and abdomen dark blue, margins behind the eyes white. Legs dark bluish grey, an ochreous spot at the apex of the posterior tibiae, all the tarsi with two or three whitish ochreous areas. Forewing narrow, apex roundish, brownish hyaline, veins, a broad costal streak as far as vein 8, the narrow anal margin and the broad discoidal mark bluish mark, fringe dark brown. Hindwing ochreous hyaline, veins black, fringe grey, a blackish brown basal shadow. 14 mm. Taperinha (July); Rio de Janeiro, Itatiaya. The insect, according to Prof. SEITZ, rests on leaves from which it does not fly off instantly, when it is disturbed, but it runs away quickly like a spider which it resembles rather much, its wings being reversed and the hairy legs projecting. On account of this peculiar exterior we figure a specimen in its natural position of repose.

34. Genus: **Albuna** Hy. Edw.

Palpi upturned as far as the height of the head, with short hair. Antennae filiform, ending fine in the ♂. Abdomen slender, anal tuft of ♂ flat and divided in the middle, forming two flat brushes. Forewing with 12 veins, 7 and 8 stalked. Posterior tibiae with short hair. Hindwing with veins 4 and 5 from the end of the cell, discocellular vein rather oblique. Type: *A. pyramidalis* Wkr.

pyramidalis. **A. pyramidalis** Wkr. (= *hylotomiformis* Wkr., *vancouverensis* Hy. Edw., *nomadaepennis* Bsd.). Head black, orbita pale yellow. Palpi yellow, black outside. Thorax black, patagia margined with yellow, behind at the thorax a yellow transverse band and a small spot at the base of the forewing. Collar yellow. Antennae black, reddish beneath. Abdomen black with pale yellow rings on each segment. Anal tuft black. Legs black, tibiae with yellow bands. Forewing transparent with broad black margins and a black cross-vein edged with red, distal and inner margins bordered with red. Beneath the margins and discal mark are covered with red and orange. Hindwing transparent, margins and cross-vein brownish black. 18—30 mm. Nova Scotia, Canada, Maine to Massachusetts. North New York and to the west as far as the Pacific. This *Aegeriida* is very variable. The imago flies from June until the middle of August; nothing is known of the early stages.

— var. **montana** Hy. Edw. (= *tanaceti* Hy. Edw.) (180 e) has yellow legs with black bands and more extensive *montana*. red on the forewing. — var. **rubescens** Hulst. (180 e) has very extensively red forewings, red-veined hindwings, *rubescens*. the abdominal rings and legs beautifully golden yellow. — var. **coloradensis** Hy. Edw. (= *torva* Hy. Edw.) *coloradensis*. (180 f) is quite black, with occasional traces of red at the inner margin of the forewing.

A. denotatus Hy. Edw. (180 e). Head and palpi black with inwardly yellow tips, orbita purely white. *denotatus*. Collar lustrous violettish black intermixed with yellow. Antennae steel-blue above, reddish below. Thorax bluish black, behind with a yellow lateral streak and a yellow shoulder-spot. Abdomen deep black, with a bluish reflection, the 2nd, 3rd, 4th, and the two last segments with broad yellow bands. Anal tuft black with traces of yellow hair. Legs black, middle and hind tibiae partly orange, the last yellow inside. Tarsi orange. Forewing violettish black with a transparent streak, all the rest as in *P. tricinatus*. According to BEUTENMÜLLER, *denotatus* may be a variety of *tricinctus*, since they are very similar, but *denotatus* has five yellow bands, *tricinctus* four in the ♂, three in the ♀. 26—28 mm. Montana, Colorado, Texas. I could not find out anything about the habits.

A. beutenmülleri Skinn. Antennae, head, palpi, thorax, abdomen, and legs black. Abdomen and thorax *beutenmülleri*. beneath metallic bluish black. Hindlegs with long black hair. Wings bright red, narrowly margined with black, fringes black. Forewing hyaline in the distal area, divided into four parts by the red veins, a hyaline streak in the centre of the wing; these hyaline areas are slightly covered with shining greenish or bluish scales, base and inner margin blackish. The hindwing has two similar spots, one near the costa, apparently bipartite by a vein, and a broader one near the base, tripartite; the base itself blackish. 20 mm. Only 1 ♀. Stockton, Utah. End of May.

35. Genus: **Tirista** Wkr.

Proboscis absent. Palpi erect, not quite reaching the head, densely scaled. Antennae strong, pectinated, growing weaker apically. Abdomen fusiform, twice as long as the thorax. Legs short, hairy, hind tibiae with four long spines. Wings narrow, veins of the usual structure. Forewing scaled, hindwing scaled in the apical half, the rest transparent. Very closely allied to *Melittia*, *Alonina* from Africa and *Paranthrene*.

T. argentifrons Wkr. ♂: black, face silvery, its posterior edge with dingy yellow fringes. Palpi reddish, *argentifrons*. yellowish apically. Chest with yellow streaks on each side. A yellow cartilaginous elevation at the base of the forewing. Abdomen red, the 2nd segment with a yellow band, the 5th, 6th and 7th quite yellow. Anal tuft yellow with a few black hairs. Legs red, tarsi golden yellow, femora black, hind tibiae beneath marked black. Forewing purple black. Hindwing transparent, bright red at the base, apical half and inner margin black. 30 mm. Oaxaca in Mexico.

T. praxila Drc. (185 c). All the wings semihyaline, yellowish brown, forewing with a darker costal *praxila*. margin and centre. On the hindwing the costal margin, apex and distal margins are edged with yellowish brown; both wings with pale yellowish brown fringes. Antennae, palpi, and legs yellowish brown. Head, thorax and abdomen darker brown, anal tuft yellow. 45 mm. Mexico: Jalapa.

36. Genus: **Sincara** Wkr.

Body rather strong. Head broad, proboscis absent. Palpi erect, thickly haired below, 3rd joint short, conical. Antennae filiform, plain, as long as the thorax. Abdomen fusiform with a small pointed anal tuft, somewhat longer than the thorax, the first segment compressed. Legs rather long and strong, the anterior tibiae with a long hair-tuft. Wings narrow, the 2nd interior vein twice as distant from the 3rd as from the 1st; 3 nearer to 2 than to 4. The 2nd upper vein bifurcates after $\frac{2}{3}$ of its length.

S. crassicornis Wkr. ♀: blackish purple, of a strong structure. Proboscis quite short. Robust club- *crassicornis*. shaped antennae slightly falciform. Abdomen fusiform, twice as long as the thorax. The two last segments and the under surface ash-grey, with a slight yellowish reflection. Legs thick, hind tibiae hairy, hind tarsi yellowish ash-grey towards joints. Forewing deep purple, distal margin rounded. Hindwing transparent, veins, margins, and fringes purple. 26—28 mm. Ega (Teffé).

S. eumeniformis Wkr. ♂: dark rust-coloured with a few silvery scales on the head and prothorax. Head *eumeniformis*. blackish. Palpi with scaly hairs at the base. Antennae bluish black. Abdomen reddish, the 1st segment brown, whitish behind. Legs blackish, with scaly stripes below, spurs light grey. Forewing delicately brown, semi-transparent. Hindwing transparent. 30 mm. Pará.

S. manoba Drc. (185 d). Forewing brownish black, darkest along the costa. Hindwing yellowish hyaline, *manoba*. fringe black. Head thorax, and abdomen dull black. Antennae black. 25 mm. Mexico: Teapa, Tabasco, February.

- phyllis*. **S. phyllis** Drc. (180 d). Forewing yellowish hyaline, brownish at the base, the costal and inner margins orange. Hindwing hyaline, fringe brown. Head, thorax and abdomen brownish black, prothorax yellowish, the 3rd abdominal segment yellow, the others with traces of yellow. Palpi and collar yellow. Antennae black, yellow at the base. Legs brown. 32 mm. Guatemala, Cerro Zunil.
- alopecura*. **S. alopecura** sp. n. (180 f). Head dark brown, silvery white between the eyes. The first joints of the antennae yellowish brown (the rest of the antennae absent). Palpi yellowish brown. Thorax brownish, slightly scaled, evidently without any further marking, lighter beneath. Abdomen rusty reddish yellow, turning brownish at the base, anal tuft lightest, almost orange. Beneath dingy whitish, opalescent, anal tuft light orange. All the legs rusty reddish yellow, the coxae turning greyish brown. Forewing yellowish hyaline, margins, veins and the indistinct discal vein brownish black, more thickly scaled in the distal area, especially the veins, where they terminate into the distal margin. Between them near the margin and at the discal mark outwardly slightly scaled yellowish hyaline. Hindwing yellowish hyaline, veins and the narrow margin brownish black, fringes of all the wings yellowish brown. 22 mm. Colombia, Umbria. 1 ♂. Type: Coll. ZUKOWSKY.
- confusa*. **S. confusa** Btlr. is an uncertain form; BUTLER places it to *S. basalis* Wkr. (176 c) and says that the antennae are very short and thick, the abdomen decidedly fusiform and differently coloured in the two sexes, though he does not dare to separate the sexes, proposing the name *confusa* for the ♀.
- lytaea*. **S. lytaea** Drc. (180 f). Forewing hyaline, yellow at the base, the costal margin and apex brownish black. Hindwing hyaline, fringe brown. Head, thorax and antennae black. Palpi greyish white below, black above. Abdomen black, each segment with fine white rings, anal tuft greyish white. Legs black, set with a few white hairs. 19—20 mm. Guatemala, Zapote.
- maeonia*. **S. maeonia** Drc. (185 f). Forewing and hindwing hyaline, the costal and distal margins of the forewing narrowly edged with black, the fringes of all the wings black, the inner margin of the forewing covered with yellow from the base almost to the anal angle. Head, thorax and abdomen black. Palpi bright yellow, tegulae striped yellow. Antennae and legs black. 25 mm. Mexico: Omilteme, Guerrero, 2700 m.
- manilia*. **S. manilia** Drc. (185 c). Forewing and hindwing yellowish hyaline, the costal margin of the forewing and the fringes of all the wings black. Head, thorax and abdomen black, the last 4 segments of the abdomen broadly edged with yellow. Anal tuft yellow. Antennae and legs black. Palpi frontally yellow. 25 mm. Mexico: Sierra de los Aguas Escondidas, Guerrero. 2400 m. July and August.
- cambyses*. **S. cambyses** Drc. (180 f). Forewing whitish hyaline, the costal margin and apex black. Hindwing hyaline, margins and fringe black. Head, thorax and abdomen black. Antennae and legs black, the tarsi mixed with a few yellow hairs. 20 mm. Panama, Bugaba.

37. Genus: **Cotaena** Wkr.

Body rather robust. Proboscis remarkably short. Palpi soft, slender, slightly bent upward, not longer than the head is broad; 3rd joint pointed, shorter than the 2nd. Antennae bristle-like, rather slender. Abdomen fusiform, its whole length projecting beyond the hindwings. Legs strong, spurs long and robust. Wings long and narrow, entirely scaled, fringes rather long. Forewing rounded at the distal margin, convex, very oblique.

- mediana*. **C. mediana** Wkr. ♀: dark metallic blue. Proboscis brownish yellow. Thorax orange, dark in front. Abdomen with a broad ochreous stripe extending from the base to half the length. Wings with dark ash-coloured fringes. Forewing orange at the base, purple towards the distal margin, under surface pale golden yellow along the costa from the base on two thirds of its length. Hindwing purple, costa pale golden yellow on $\frac{3}{4}$ of its length. 32—34 mm. Pará.

38. Genus: **Ecrectica** Wkr.

Body slender, straight. Proboscis absent. Palpi compressed, slender, hairy, erect, much longer than the head is broad, the 3rd joint with an obtuse point, shorter than the 2nd. Antennae hairy. Abdomen with its whole length projecting beyond the hindwings. Anal tuft quadrangular. Legs scaled, rather long and slender, hind tibiae without middle spurs. Wings long, narrow, scaled. Forewing rather rounded outside, distal margin uncommonly oblique.

- fasciata*. **E. fasciata** Wkr. ♂: dark copper-coloured. Palpi and antennae black. Thorax red at the anterior edge. Abdomen beautifully red, except the apex. Hind tibiae with yellow bands towards the joints, hind tarsi basally yellow. Forewing yellow at the base with an irregular postmedian band. 25 mm. Ega (Teffé).

39. Genus: **Parharmonia** Beut.

Palpi extending forward, with appressed scales. Antennae long, filiform. Abdomen slender with a straight insignificant anal tuft. Hind tibiae with short hair. Forewing with 12 veins, 7 and 8 stalked. Hindwing: 4 and 5 on a short stalk at the end of the cell, vein 1a traceable, discocellular vein oblique. Proboscis developed. Type: *P. pini* Kell.

P. pini Kell. (180 g). Head, palpi, antennae, thorax and legs metallic blue or greenish blue. Collar in *pini*. front somewhat orange. Abdomen above black, the posterior half of the 4th segment orange, under surface and the anal tuft quite orange. Forewing metallic blue or greenish black, with a still more prominent discal mark. Hindwing scantily covered with bluish black scales, almost transparent with very narrow black margins. 28—30 mm. Canada, New York, New Jersey, New Hampshire. — Larva in pine-trees underneath the bark and in the upper wood in curved passages, indicated by semiglobular gall-like formations interspersed with resin, frequently situate very high on the trunks or twigs. The pupation takes place in a silky cocoon in the hardened excrescences in May, June. The imago appears in June till August.

P. piceae Dyar. Bluish black. All the wings hyaline, forewing with a black costal margin, the cross-vein and the distal margin also black, the apex broadly black. Antennae black. The interior edge of the patagia red. Palpi inside at the base, anterior coxae outside, and irregular spots on the inside of all the tibiae also red, anterior tarsi reddish, middle tarsi inside reddish, posterior tarsi black. Abdomen with scattered red scales on the under surface, forming a defined double spot on the 3rd segment, unicoloured black above. 25 mm. Hoquiam, Keyport (Washington). — The larva lives in *Picea sitchensis*.

40. Genus: **Sophona** Wkr.

Body rather long. Proboscis mostly absent. Palpi moderately long, slightly hairy, the 3rd joint pointed. Antennae bristle-shaped, hairy below, as long as the thorax. Abdomen fusiform, more than twice as long as the thorax, with a feeble anal tuft. Legs strong, tibiae with hair-tufts in the middle and at the end. Hind tarsi very thickly and strongly haired. Wings very narrow, forewing scaled, hindwing transparent.

S. halictipennis Wkr. ♀: purple. Head whitish. Palpi whitish, black beneath. Thorax with three yellow stripes. Abdomen with a narrow yellow band near the base, white beneath. Tibiae and tarsi chiefly brownish yellow, the tibiae with black hair-tufts. Forewing purple black with ash-coloured distal marks. Hindwing almost quite transparent. 18 mm. Villa nova. — **flavizonata** subsp. nov. (180 g). Collar, between the eyes, as well as the anterior coxae light yellow, no stripes on the thorax. Abdomen as in the nomenclatural form with a narrow yellow band near the base, the last three segments posteriorly edged with light yellow, the anal tuft light orange. Legs as in *halictipennis*, black above, light grey beneath. Forewing purple black, semitransparent in the distal area, hindwing transparent. 15 mm. Rio de Janeiro. Collected by Prof. SEITZ. Type: Senckenberg Museum at Frankfurt on the Main.

41. Genus: **Bembecia** Hbn.

Palpi erect, but not reaching the head, with rather long hair at the origin. Head small, thorax convex in front. Abdomen strong, with somewhat projecting hair on the 1st and 2nd segments. Anal tuft of the ♂ short, broad and flat, insignificant in the ♀. Middle and hind femora as well as tibiae hairy. Antennae short, dentate in the ♂, plain in the ♀. Proboscis absent. Forewing with 11 veins, 7 and 8 stalked, 2 absent. Distal margin of hindwing curved, the veins 4 and 5 on a long stalk, 3 parallel with it. Discocellular vein straight. Type: *B. hylaeiformis* Lasp. from Europe.

B. marginata Harr. (= *placciaeformis* Grt., *odyneripennis* Wkr., *rubi* Riley, *flavipes* Hulst.) (180 f). Head brown, orbita, palpi and collar yellow. Antennae black. Thorax deep brownish black with yellow markings. Abdomen deep brownish black with yellow rings on the posterior part of each segment, extending all around. Anal tuft yellow and black; quite yellow in the ♀ like the last segment, too. Legs yellow, femora and tibiae outside partly black. Forewing transparent with broad brown margins, a lighter inner margin and intense discal marking. Under surface more yellow, especially at the base. Hindwing with a narrow brown margin, all the veins brown. 20—35 mm. August, September. Canada to the west as far as the Gulf of Georgia, Vancouver, New England, Central States to the west as far as Ohio, Illinois, Missouri, Kansas, and Nebraska. The eggs are singly deposited on the lower parts of the stalks of blackberry and raspberry, from where the larva penetrates into the crown of the root; the adult larva goes into the old stalks of the previous year, where it pupates. The pupa has a sharp three-edged point on its head for piercing the outward skin, while it emerges. The species is the counterpart of the palaearctic *hylaeiformis*. — var. **albicoma** Hulst. Head, thorax and abdomen deep sooty black with very pale yellow, almost white rings. The yellow is also less extensive, so that the three first segments are mostly quite black. Legs with more black. Otherwise like *marginata*. 23—27 mm. New York and New Jersey.

eucheripennis. **B. eucheripennis** Bsd. Head and antennae rusty brown. Thorax unicoloured iron-brown. Abdomen violetish black, all the segments edged with rust-brown, the two first yellow behind, at the base of the abdomen there is also yellow colouring. Feet bright rusty red, the anterior parts black. Forewing transparent, broadly brown outside, the margins as well as the discal vein brown, the latter lighter outside, bordered with rust-colour. Hindwing transparent with a narrow blackish margin and blackish veins. 30 mm. Mexico.

42. Genus: **Myrmecosphecia** Le Cerf.

Head small, not convex. Palpi short, thick, the first joint below with a hair-tuft. Antennae short, scarcely longer than the thorax, below in the middle set with hair-shaped scales. Eyes small. Proboscis well developed. Body thick and strong, abdomen cylindrical-conical, anal tuft small. Wings long and stretched, the cell of the forewing therefore also very long, occupying three quarters of the wing. Vein 1 obsolete, 2 absent, 3 from the interior angle of the cell, 4 nearer to 3 than to 5, 7 and 8 not stalked, arising from the upper angle of the cell, 9 and 10 at equal distances, 11 separated far from 10. Hindwing: 1a absent, 2 and 3 very near together and separated far from 4, 4 arises from the interior angle of the cell, 5 from the discocellular angle, 6 absent, 7 placed obliquely to 5. Type: *M. Le Moulti* Le Cerf.

moulti. **M. Le Moulti** Le Cerf (180 g). Head and palpi black, the 3rd joint below black. Antennae black, reddish at the ends. Collar, thorax and abdomen bronze black, abdomen reflecting, except the three first segments which are without lustre, their sides being covered with reddish scales. Ventrums bronze black, the 4th segment white beneath. All the legs bronze black, the femora whitish inside. Forewing black, feebly rust-coloured in the cell, the exterior third transparent, the margins and fringe black. Hindwing transparent, veins and margins very finely black, short black fringes. 32 mm. 1 ♀. French Guiana. June. Superficially similar to *A. ovinia* (178 h) and *S. manoba* (185 d).

Family: Cossidae.

Considering the *Cossidae* and their distribution over the Earth in general we must bear in mind that frequently species have been ranged in this family, the propinquity of which has not yet been fully proved. The peculiar life-habits of the larvae of this family in the interior of plants — especially of wood-plants — has produced quite a number of exterior features which may easily mislead the systematizer, wherever they are not distinctly exhibited as convergencies. Not even the delimitation of the family had thus far been fixed, and the insertion of the *Arbelidae* of America (*Lepidarbelidae*) in the *Cossidae* has only at this place been really carried through, although it had been practically employed long ago in statistic works (REBEL).

Towards the end of the last century, KIRBY compiled in his Catalogue about 218 species which are almost equally divided upon the four large faunae. Somewhat later, REBEL enumerated already twice as many (440) species, and to-day 70 more species have been superadded to this total number. Yet the rather equable distribution over the Earth has remained, since each of the three faunae of the Old World harbours about 100 species (the Palaearctic and Ethiopian Regions somewhat less, the Indo-Australian Region somewhat more), only the American Region holds twice as many species, about 200.

The life-conditions of the *Cossidae* are such as allow them to occur nearly on the whole of the Earth, only smaller islands being often without any, especially also New Zealand which is unintelligibly poor in Macrolepidoptera.

The bitterest enemy of the *Cossidae* as imago, at least in South America, is the bat. As we mentioned already in Vol. XIV, the imagines are attracted to the light from great distances, whizzing round the lamps in a straight, somewhat unwieldy flight, while the bats spread mighty havoc among them. I could observe this especially in the larger *Langsdorfia* in Brazil and was struck by this fact all the more since I never noticed that the *Zeuzera pyrina* which are indigenous to the palaearctic region (but imported into America) were pursued by bats. The ♂♂ of *Zeuzera pyrina* mostly dashed upon the flame, and after having hit against the window-panes with their heads, they dropped straightway to the ground. There they remained lying motionless on their backs, with their wings closely appressed, and sometimes numbers of them were lying about even in the morning, similarly as if cigarette-ends had been thrown away. As they were neither attacked by the large panther-toads, which search the ground beneath the lanterns at night in North Africa, it seems that certain species are protected by pungent or perhaps obnoxious saps, which would also explain the experience made in Europe with chickens despising the *Zeuzera pyrina* that were thrown to them among other moths which they greedily devoured. The American *Cossidae* are rarely met with except in the lamp-light, because many species are well protected by their bark-like colouring, and besides they live rather well hidden. The smaller forms of the steppes even seem to hide beneath or close to the soil, for even those species which, like the Argentine *Langsdorfia ambigua*, are whirling around the lamp in tremendous swarms and which must consequently occur in immense numbers of individuals, are hardly ever or never met with in the daytime. In searching for larvae at night with a lantern, the imagines of the genus *Holcocerus*, which are hardly ever come upon in daylight, can be observed creeping up stalks and blades projecting beyond the scanty sward of the steppe; consequently, they must also have their hiding-places on the soil.

Regarding the life-history of the American *Cossidae*, we are only informed to some extent about the nearctic species. They do not differ in this from those of other faunae. The duration of life of the larva is very long as in most of the wood-eating insects; presumably owing to the lignified parts of the plants being not very nutritious, and because of the boring which they are forced to do being very wearisome. On the one hand, it is the long duration of this time of development, during which the larvae are exposed to all kinds of dangers, on the other hand the great number of foes living on the invariably fat larvae of the woodborers, that the number of individuals reaching puberty is greatly reduced in spite of their concealed habits. The wood-larvae are enormously decimated by termites and rapacious beetles inside the passages, by wood-peckers and Hymenoptera

outside. The number of eggs produced by some ♀♀ of the *Cossidae* is therefore amazingly great, and if in certain years favourable conditions of life are presented to the *Cossidae* owing to the non-appearance of certain enemies or to climatic constellations, the number of certain species may sometimes be so tremendous that they almost resemble a swarm of locusts.

The American *Cossidae* exhibit numerous schemes of colouring that are well known from other faunae. The *Zeuzera pyrina* which we already mentioned to have been imported, has not yet changed in America, while in North Africa it invariably shows a different thoracal marking compared with the European species. In America, especially in the nearctic region, we also find the approximate exterior of the palaearctic *Cóssus cossus* in quite a number of species; some of them have even been described as *Cossus*, as for instance *Acossus ore Strecker*; *A. populi* from the Hudson Bay and *undosus* from the Rocky Mountains are extremely similar to North Asiatic forms of *cossus*, except that the shade of the grey groundcolour has slightly changed according to the bark of the food-trees. *Miacore diffidens Dyar* from Mexico exhibits a colouring and marking very similar to that of *Cossus terebra*, and also other species occur in America, which show a great resemblance to the smaller Egyptian *Cossus*-species and some Central Asiatic species, such as the recently discovered *C. sheljuzhkoii Zuk.* from the Thian-shan.

The marking of the Cossid wing being adapted to rimous bark as well as the imitation of broken off little twigs represents an assimilation of nearctic *Cossidae* to palaearctic Heterocera, which is merely due to convergency and therefore accidental. The image of the resting *Phalera bucephala* most strikingly copying a piece of twig by the way it holds its wings and by showing the broken part, reoccurs in American *Cossidae*, as in *Cossula magna Schs.* from Guiana and the likewise similarly marked *Cossula gaudeator Schs.* from Costa Rica. As we mentioned above, it is extremely risky to conclude affinities from the colouring, marking and even the exterior habitus, yet it seems that in classifying some very similar species in distantly separated genera, the characteristic structure has sometimes been considered too exclusively, as we must not ignore an extraordinary polyformism, for instance of the antennae in the *Cossidae*. It was chiefly the shape of the antennae, which started the idea of dividing the *Cossidae* into two entirely separated families — the *Cossidae* and *Zeuzeridae*. In nearly all the other Heterocera families it is advisable to concede the shape of the antennae an essential influence upon the construction of the system, but in single cases the structure of the antennae is most probably caused by certain conditions of life, which being sometimes due to the landscape change the function of certain organs and thereby also their structure; we merely remind our readers of the differences of the antennae in certain species from other groups, which are otherwise extremely similar and evidently very closely allied, as for instance *Brephos parthenias L.* and *notha Hbn.*

Family: Cossidae.

By H. G. DYAR †. (Revised by Dr. W. SCHAUS.)

Already in 1894 I divided, together with B. NEUMOEGEN, the *Cossidae* for the first time into two subordinate families according to the presence or absence of a cross-vein between the veins 7 and 8 of the hindwing. This classification was kept up by SCHAUS for the genera of the South American *Cossidae*, considering at the same time the formation of the antennae. In 1911, BARNES & MC DUNNOUGH supplied an excellent key to the North American forms of this family, in which the aforementioned characters were ascertained to be subject to a certain variability; they therefore proposed to give up this division. Instead of it they proposed as a basis for a better classification to use as distinguishing characters the variations of the anal veins of the forewing, according to these veins being united near the margin or extending separately.

The collection of the National Museum at Washington contains now the collections of both SCHAUS and DOGNIN, being the main describers of the American species of this family, beside HERBERT DRUCE, so that most of all the species known are present there. In trying to range these species among the corresponding genera I came across a species (*Lentagena ophelia Schs.*) which renders also the division of BARNES & MC DUNNOUGH impossible. But as this species corresponds well with *Carohamilia Dyar* in all the other characters, it shows that this cannot be used for diagnoses either.

Consequently, I have been looking for another principle of classification for the American species and have likewise used for it the neurulation of the forewing. Vein 11 arises from the areole in *Xyleutes*, *Cossula* etc., from the centre of the discal cell in the others, for which reason I choose this character as a division. HAMPSON proposed to divide the *Cossidae* into two families, the *Hypocptidae* without a frenulum and the *Cossidae* with a frenulum, but I found this character not to be suitable for the classification of the genera.

Judging from the material at hand, no species of the family of *Lepidarbelidae* occur in America. This family — formerly named *Arbelidae* (according to *Arbela Mr.*, a homonym of *Arbela Stål*) — is closely allied with the *Cossidae*. The latest catalogue by DALLA TORRE and STRAND enumerates 9 American “*Lepidarbelidae*”. Only 7 of these are known as genuine *Cossidae*, quoted here as *Cossula* and *Givira*. The two others will probably also belong to this place.

LEACH, in 1815, was the first who used the name of *Cossidae* for denoting the *Cossus* and their allies as a group, for which reason the family must bear his name as the author's name. The typical genus is *Cossus* F. (1794) with the typical species: *cossus* L. (1758).

Key to the American Genera.

- I. Vein 11 of forewing from the areole or close before its origin **Zeuzerinae.**
 1. Areole long and narrow, projecting beyond the end of the discal cell.
 - a) Sexes dissimilar. Hindwing of ♂ triangular *Cryptobia* H.-Schäff.
 - b) Sexes similar.
 - a₁ Discal vein of forewing forked,
 - a₂ Veins 7 and 8 of forewing stalked,
 - a₃ Veins 7 and 8 of hindwing separated *Xyleutes* Hbn.
 - b₃ Veins 7 and 8 of hindwing connected by a cross-vein *Zeuzera* Latr.
 - b₂ Veins 7—10 free, near the end of the areole *Schreiteria* Dyar
 - b₁ Discal vein of forewing not forked *Carohamilia* Dyar
 2. Areole short and obtuse, not projecting beyond the discal cell
 - a) Veins 7—9 of forewing stalked, or 7 connected with the base of the stalk of 8 and 9 *Trigena* Dyar
 - b) Vein 7 remote from the stalk of 8 + 9, or the veins separated, 9 sometimes stalked with 10 *Cossula* Bailey
- II. Vein 11 of forewing from the centre of the discal cell **Cossinae.**
 1. Forewing with separated anal veins.
 - a) Discal veins of forewing and hindwing not forked. *Heterocoma* B. & McD.
 - b) Discal vein of forewing forked, of hindwing plain
 - a₁ Cell of hindwing moderately long *Miacora* Dyar
 - b₁ Lower cell-angle very long, $\frac{3}{4}$ of the length of the wing *Psychopsis* Dyar
 - c) Discal vein forked in both wings
 - a₁ Veins 7 and 8 of hindwing free (with rare exceptions)
 - a₂ Cell of hindwing rounded *Chilecomadia* Dyar
 - b₂ Cell of hindwing inwardly angled
 - a₃ Veins 6 and 7 of hindwing from the same base *Hypopta* Hbn.
 - b₃ Veins 6 and 7 of hindwing separated, connected by a bar behind the cell *Pernambis* Schs.
 - b₁ Veins 7 and 8 of hindwing connected by a bar
 - a₂ Sexes similar; thorax densely clad *Acossus* Dyar
 - b₂ Sexes dissimilar; thorax thinly clad *Prionoxystus* Grt.
 2. Anal veins of forewing connected by a bar or united near the margin
 - a) Discal vein forked in both wings
 - a₁ Veins 6 and 7 of hindwing from one base or stalked
 - a₂ Hindwing rounded, normal *Givira* Wkr.
 - b₂ ♂ hindwing triangular *Psychogena* Schs.
 - b₁ Veins 6 and 7 of hindwing separated, almost parallel *Langsdorfia* Hbn.
 - b) Discal veins not forked in both wings
 - a₁ Veins 6 and 7 of hindwing stalked *Puseyia* Dyar
 - b₁ Veins 6 and 7 of hindwing separated, almost parallel *Inguromorpha* H. Edw.

1. Genus: **Cryptobia** H.-Schäff.

The ♀♀ are large strong insects, the ♂♂ much smaller and of a darker colouring. ♂ antennae pectinated only in the basal halves, plain in the ♀. Vein 11 of forewing arises close before the base of the long narrow areole which extends far behind the discal cell from the apex of which 7 and 8 arise stalked, 9 arising from the base of the stalk; 10 shortly before it; the discal veins are broadly forked in both wings. 6 and 7 of the hindwing arise distantly separated, 8 free.

Type: *C. mucorea* H.-Schäff.

C. mucorea H.-Schäff. (181 a) is at once discernible by the yellow hindwing with a narrow margin. The *mucorea*. brown ground of the forewing is striped brownish black. Brazil.

C. musae H.-Schäff. (= *muscae* Ky.) (181 a). HERRICH-SCHÄFFER figures a ♀ from the Rio Grande. *musae*. in the National Museum there are specimens from Mexico, Central America, Ecuador, and Colombia. The ab-

domen is densely clad with black spatulate hair. Both wings are finely reticulated with black, creating the impression of a large *Neuroptera*. The ♂ is indistinctly marked, the ♀ exhibits a large quadrangular blackish spot at the cell-end and a few irregularly angled black lines and small spots between the veins at the apex of the wing. If — as the name says — the larva of this large *Cossida* bores in the trunk of bananas, it would surely do much harm occasionally, yet nothing has been reported about this so far.

phobifera.

C. phobifera *sp. n.* Wings long and narrow, the hindwing sharply triangular, excavated at the distal margin. Forewing dark brown, black at the costal and inner margins, the colours unnoticeably passing over into each other, veins blackened, the ground-colour scantily strewn light. Body black, the thorax in front projecting far beyond the bases of the forewings. Hindwing black. Expanse of wings: 32 mm. According to a much damaged ♂ specimen, the distal margins of the forewings broken, the hindwings partly without scales. The type in the National Museum at Washington. Paraguay, Villa Rica, taken in March (P. JÖRGENSEN).

2. Genus: **Xyleutes** Hbn.

Both sexes similarly marked, the ♀♀ much larger than the ♂♂ and generally somewhat more indistinctly marked. Forewing with a long narrow areole, projecting far behind the cell, veins 7 and 8 arising stalked from its apex, 9 united with them or on a short stalk; 10 arises from before the end of the areole, 11 from near its base; discal vein forked in both wings. Cell of hindwing flatly incurved, veins 7 and 8 remote from each other, 8 free. ♂ antennae bipectinate in the basal halves, plain at the tips, plain in the ♀.

Type: *X. crassa* Drury from West Africa.

xylotriba.

X. xylotriba *H.-Schäff.* (181 b, c). A very large species, the thorax covered with dingy white scales. Forewing broadly wood-brown along the costal margin almost to the apex, more or less lighter yellowish along the middle, bordered below by an irregular black band which is several times angularly indented or interrupted, so that a quadrangular spot is in the centre. Interior area dingy white, reticulated black, the inner margin shaded darker. Hindwing shaded dull wood-brownish, the reticular marking often blurred. ♀ lighter and less distinctly marked, only slightly brown at the costal margin. Costa Rica to Argentina.

ramosa.

X. ramosa *Schs.* (= *aetes* *Drc.*, *ramuscula* *Dyar*) (181 c). Small or medium-sized, the costal-marginal half of the forewing rusty brownish, turning more blackish at its upper and lower edges with a black dent along the base of vein 2 as far as the submedian vein; this brown area generally reaches the apex, not always in more southern specimens (from Brazil and Bolivia); the interior half of the wing is white with vertical black striae which are reticularly confluent at the distal margin. Hindwing white. ♀ with more rounded wings, similar markings, the hindwing dark grey. Texas, Mexico, Guatemala, Costa Rica, Panama, Colombia, Bolivia, Brazil, Paraguay.

desdemona.

X. desdemona *sp. n.* Head and collar black, thorax and abdomen dingy white. Costal half of forewing quite blackish brown except a few black reticular markings towards the distal margin; interior half dingy white, striated black, assuming a reticular marking towards the margin. Hindwing tinged with grey. It may be merely a form of *ramosa*, though none of my 37 specimens agrees with them. According to 1 ♂ from Espiritu Santo, the type in the U. S. National Museum, November (J. ARP, Coll. DOGNIN).

pyracmon.

X. pyracmon *Cr.* (= *pyracmonides* *Schs.*, *putrida* *Perch.*, *palmarum* *H.-Schäff.*, *cognata* *Drc.* nec *Wkr.*), *fracta* *Wkr.* (181 d) is a well known and common species; forewing dingy white, with black transverse striae, more reticulated outwardly; a large blackish brown wedge at the base of the costal margin, connected with, or separated from, a brown undulated longitudinal band through the centre of the wing growing narrower outward. Hindwing more or less tinged with brown, reticulated towards the margin. Fringe spotted black. The ♀ is larger, the markings are sometimes very indistinct. —

lelex.

lelex *Dgn.* is based upon an indistinctly marked ♀ from Merida (Venezuela), but similar specimens may be occasionally found everywhere. Mexico to Brazil. The larva presumably bores in the trunks of palms, if HERRICH-SCHÄFFER's name be well founded.

strigillata.

X. strigillata *Fldr.* resembles *pyracmon*, but the body and wings are throughout dull smoky brown, the dark longitudinal band on the forewing is black. From Argentina.

melanoleuca.

X. melanoleuca *Burm.* is a dark smoky brown species like *strigillata*, but the markings are more distinctly reticular and the dark longitudinal band is divided into 3 spots, the basal costal-marginal spot of which is quite indistinct, the middle one quadrangular, and the exterior one thin. Argentina.

masoni.

X. masoni *Schs.* (167 e). Body and forewing light smoky grey, the black central longitudinal band is narrow in the basal third of the costal margin and in the lower half of the cell as well as at the base of the veins 4 and 5, and bordered below by a broad dull brown area which extends to the submedian vein; a discal

spot is often traceable and occasionally also a black streak at the end of the areole and along the stalk of the veins 7 and 8. Mexico, Guatemala.

H. comisteon *Schs.* (167 e). Dingy white like *pyracmon*; the longitudinal stripe is brown, somewhat ex-*comisteon*. tinct, a costal-marginal spot is in the second distal third; the markings consist of brown transverse striae which are only here and there forked or reticular. Costa Rica; Panama.

X. discreta *sp. n.* (167 e) is smaller than *comisteon*, though the size is of little importance in this group; *discreta* the central band is dark brown, distinctly marked, coherent; the brown striae distinct, not any of them being reticularly confluent with another. Hindwing reticulated with many striae which are absent in *comisteon*. Body very densely and abundantly clad with dingy white scales, white and smooth in *comisteon*. Type: 1 ♂ from Brazil (J. ARP, Coll. DOGNIN) in the U. S. National Museum.

X. cognata *Wkr.* (= *mathani Schs.*, *oberthuri Houlb.*, *mexicana Houlb.*) (181 d). Dingy whitish and *cognata*. marked like *pyracmon*, but the markings are composed of small distinct spots, often circular, never reticular; the markings are generally brownish black, sometimes also of a brown tan-colour. The species varies much in size like all the *Cossidae* do. *cognata* was founded upon a small specimen, *mexicana* is the same. SCHAUS and HOULBERT considered the larger specimens (*mathani* and *oberthuri*) to be separate species, but I cannot find the least specific difference between them. From Mexico to Brazil and Peru.

X. strigifera *Dyar* (181 d). Dingy white, the forewing with rather densely arranged thick greyish black *strigifera*. striae which are irregularly confluent at the cell-end, forming a discal spot which has often a bent shape; costal margin densely spotted; a smaller species, generally smaller than *ramosa Schs.* Mexico and Central America.

X. albogrisea *Dogn.* (167 f). Forewing throughout dingy dark grey, the markings only traceable as *albogrisea*. brownish grey clouds, a broader brownish one of which cuts off the basal area obliquely, a more or less developed broad brown median band is also present. A diminutive species from the Amazon Region of Brazil. This small insignificant *Cossida* presumably represents the southernmost branch of the following group.

Subordinate group: **Psychonoctua** *Grt.*

The following 12 species represent a group widely distributed in the Antilles, on the northern coast of the continent, and from Arizona through Mexico to Central America. It is so difficult to distinguish them specifically, that I found it best to separate them geographically. The larvae bore in the trunk of coffee, in the Antilles in Cassia. Each island seems to have its particular species. On the continent there are at least two species which have a very wide range.

X. jamaicensis *Schs.* Light grey, slightly clouded and reticulated darker; a broad dark basal area is *jamaicensis*. somewhat obliquely cut off outside; a round black dot in the disc; there are often traces of a broad brown shadow through the centre of the wing as in *albogrisea*. The ♀ has less distinct markings, the dark basal area is brownish and faded. Jamaica.

X. lillianae *Linds.* (167 f) is exactly like *jamaicensis* except the somewhat lighter colouring; the dark *lillianae*. basal area of the forewing is pale, somewhat more obliquely cut off and receding a little below the cell; the brown central shadow is absent, but the discal dot is black. The ♀ is more faded brownish, the dark basal area is entirely absent, the discal dot is indistinct or quite absent, the ground indistinctly striated. From Antigua, Montserrat, and Barbados. The specimens before me were bred on coffee and Cassia glauca.

X. muricolora *sp. n.* scarcely differs from *lillianae*, the dark markings are still more indistinct. The ♀♀ *muricolora*. are grey with but feeble traces of the rosy brown suffusion of *lillianae*. From Porto Rico, bred on coffee. Type from Aguadilla (Porto Rico), in January, in the U. S. National Museum.

X. personalis *Grt.* (167 f) shows very contrasting colours, the striae insignificant or obsolete: the light *personalis*. grey ground-colour predominates; the discal spot is black and distinct, the basal area likewise distinct, but confined to a stripe along the costal margin, the brown median band is generally distinct. The ♀ exhibits distinct black striae on a purely grey ground, the discal dot moderately distinct, the basal area not dark. Cuba.

X. benestriata *Hmps.* This form which is not at hand has, according to HAMPSON, whitish forewings *benestriata*. scantily marked with scattered brown striae which are black behind the middle of the costal margin; a small

black lunule at the cell-end; apparently there is no dark basal spot. Described according to 1 ♂ from the Bahamas (Abaco).

punctifera. **X. punctifera** *Hmps.* Smoky brownish grey, the striae often faded; a dark basal area is usually absent, but traceable in some specimens; discal dot absent, but a small quadrangular spot in the submedian area below the base of vein 2. The ♀ shows rather the same colouring as the ♂, with faded striations, but without any dark markings. Grenada.

poam. **X. poam** *Dyar* (167 f) is a robust species of variable sizes with narrow, apically pointed forewings. Dingy white, the grey striae scanty, but clear, the dark basal area intermixed with blacker streaks and bordered by an indistinct line extending obliquely inward. Above the black discal spot at the costal margin there is more or less blackish shading, also in the submedian area below it. The ♀ is apparently not yet known. Mexico, Guatemala.

atra. **X. atra** *B. & McD.* (181 e). Forewing narrow, only slightly pointed at the apex, all over shaded with dark grey, the dark striae faded; an oblique indistinct subbasal line indicates the border of the dark basal area. Arizona; Mexico (Tehuacan), in September.

gilensis. **X. gilensis** *B. & McD.* (167 f) I only know from the figure; a small species with rather obtusely rounded forewings, the dark basal area distinctly reticulated, and distinctly defined at the distal margin; a line of intensified reticular markings extends through the centre of the wing. Arizona.

unilinea. **X. unilinea** *Dyar* (181 e) is a small species with obtusely rounded wings, light grey, scantily striated; the dark basal area is marked by a distinct oblique black line; a single darker strigiform spot behind the middle of the costal margin. Mexico. I am convinced that this species is the same as *gilensis*.

terrafirma. **X. terrafirma** *Schs.* (= *nullifer* *Dyar*) (181 f). A smaller or larger species, generally light grey, but sometimes suffused with a warm red colour; the striae show an inclination to reticulation, especially towards the distal margin; discal dot distinct, the dark basal area very oblique, and notched in its lower part, so that it is chiefly confined to the costal-marginal part. The only ♀ at hand, the type of *nullifer*, shows no markings and is of a greyish salmon-colour. A few ♂♂ from the same habitat are marked very light and likewise suffused with salmon-colour, while others from the same habitat are normally marked and without a reddish tint. Specimens from Colombia (Coll. DOGNIN) belong to the normal grey form. Costa Rica; Panama; Colombia.

xuna. **X. xuna** *sp. n.* (181 f). Like *terrafirma*, but with broader wings, less pointed at the apex. The colouring is almost grey, less whitish than *terrafirma*, the dark basal area rather brown than black, less notched below the costal-marginal part. Wings with distinct postmedian reticular markings; discal dot small, black. Type: 1 ♂ from Mexico (Colima), April, in the U. S. National Museum.

3. Genus: **Zeuzera** *Latr.*

Neuration same as of *Xylentes* except vein 11 of the forewing arising from the cell before the origin of the areole; 6 and 7 of hindwing connected by a strong bar which forms a part of the cell-end. In America but one species exists, imported from Europe. *Z. canadensis* *H.-Schäff.* evidently belongs to *Azygophleps asylas* *Cr.* from Africa and is wrongly labelled.

pyrina. **P. pyrina** *L.* (= *aesculi* *L.*, *decipiens* *Ky.*) (Vol. II, pl. 52 g). White, scantily scaled. Thorax with six small black spots, the abdomen also spotted. Wings with small oval bluish black spots in rows between the veins. Atlantic Coast, Massachusetts, New York and New Jersey, evidently spreading farther. The larva bores in elms and other trees.

4. Genus: **Schreiteria** *gen. nov.*

Forewing with a very long and narrow areole extending basad as far as the centre of the cell, the lower branch being delicate; discal vein long-forked; 7, 8 and 9 arise separately from the end of the areole, 10 from before its end, 11 from its basal third. Cell of hindwing flatly angled, discal vein broad and long-forked, 6 and 7 separated and parallel, 8 free. Three quarters or more of the antennae are pectinated, the pectinations decreasing in length towards the end, ♀ antennae plain.

Only 1 species:

pectinicornis. **S. pectinicornis** *sp. n.* (167 g). Dingy silvery white marked with small black spots and striae, with dense transverse internerval striae which turn into small round spots in the basal part of the cell, basally forming a condensation which is oblique, but not distinctly defined; the cell and the area right below it less spotted, so that there seems to be a lighter band; at the cell-end the spots are denser, behind them again a lighter area, below which the striae are denser, so that a darker shadow crosses the disc, behind it more uniformly and scantily

striated as far as the margin. Hindwing white, tinged with grey in the ♀, with rows of grey striae between the veins, which are more numerous and darker in the ♀. Expanse of wings: ♂ 35, ♀ 46 mm. Argentina (Tucuman), types in the U. S. National Museum.

5. Genus: **Carohamilia** *gen. nov.*

Areole long, triangular, 7 and 8 arise stalked from its apex, also 9; 10 close before it, and 11 near the base; discal vein plain, shortly forked only in one specimen. Discal vein of hindwing shortly forked, 6 and 7 separate and parallel, 8 free. The type of the genus shows the anal veins of the forewing connected by a bar near the margin, while they are free in the other species.

Type: *C. ophelia* Schs.

C. ophelia Schs. resembles a small dark-coloured *H. terrafirma* (181 f); basal area small, uniformly dark, *ophelia*. obliquely cut off, a small spot at the costal margin above the distinct discal dot; reticular markings fine, clear, grey, but not conspicuous. Guatemala.

C. itys Drc. Dingy white, alternately grey and white between the reticular markings in the distal half; *itys*. a subbasal oblique black band composed of 2 confluent spots situate at the costal margin and in the submedian area; a similar spot at the distal third of the costal margin; the striae are distinctly connected reticularly, large and clear, uniformly scattered over the whole wing. Colombia.

C. lineaplana Dgn. (167 g). Dingy white, the forewing densely striated black, not only between the *lineaplana*. veins, but single striae cross them; hindwing not striated. In half of the specimens at hand veins 7 and 8 of the hindwing are connected by a bar which, however, is only delicate and not as in *Zeuzera*. The discal vein is mostly plain, in two specimens it is forked on the hindwing. French Guiana; Amazons (Obidos).

6. Genus: **Trigena** Dyar.

Veins 2—5 of forewing arise radially from the lower cell-angle; discal vein long-forked, the areole long, oval, its lower branch delicate, not projecting beyond the end of the 3rd discal cell; 7—9 stalked (or 9 connected with the base of the stalk); 10 arises from the areole and 11 from its centre. Cell of hindwing not notched, uniformly rounded, all the veins separate, 8 free; discal vein long-forked. ♂ antennae bipectinated to the tips, those of the ♀ singly long pectinated to the tips. This difference of the sexes is very remarkable and induced me 26 years ago to place all the ♀♀ to the genus *Hemipecten* Dyar, the ♂♂ to *Trigena*.

Type: *T. parilis* Schs.

T. parilis Schs. (= *ecparilis* Schs.) (181 f). Forewing dark blackish brown with coarse black reticulations *parilis*. intermixed with finer ones; the coarse ones form a submarginal line which usually forms a loop or a circle at the height of the cell. Hindwing dingy white, reticularly striated brown in the ♂, the ♀ tinged with a deeper brown. Brazil (Rio de Janeiro).

T. horrifera Schs. Only the ♂ is at hand, it is larger and darker than *parilis* (181 f), with somewhat *horrifera*. differently arranged reticular markings on the forewing. Brazil (Rio de Janeiro).

T. crassa Schs. is exactly like *parilis* (181 f). Hindwing light, whitish in the disc, the coarse black reticular markings on the forewing more rectilinear, almost linearly arranged. Costa Rica and San Salvador.

T. amarosa Dyar (181 b). Forewing dark lilac grey, the thick black striae form well marked subbasal, *amarosa*. median and subterminal lines. Hindwing white, only the anal area feebly shaded. Mexico (Cuernavaca).

7. Genus: **Cossula** Bailey.

A considerable number of species with a variable neuration, similar to *Trigena*. All the veins may arise separately, or 7, 8 stalked, 8, 9 stalked, or 9, 10 stalked, but 7 is never stalked with 8 and 9 as in *Trigena*. The ♂♂ have an enormously long frenulum thorn, half as long as the whole hindwing, extending into a noose of the subcosta of the forewing, while the ♀♀ exhibit a small tuft of bristles. Antennae pectinated or bipectinated, but without a sexual difference, at least as far as one can judge from the ♀♀ at hand.

C. coerulescens Schs. (182 g). Blackish, with greenish white diffuse streaks in the submedian area, a *coerulescens*. fiery red spot traversed by darker veins in the marginal area, traversed by a curved black band. Hindwing black with an intense violettish blue reflection. Veins 7 and 8 of forewing distantly separated, arising from the

exterior edge of the areole, 9 and 10 on a short stalk from its apex, 11 from its centre. ♀ not known. Costa Rica.

- abnoba*. **C. abnoba** Schs. (167 g). Dark violettish grey with white scales in the submedian area and before the marginal spot which is yellow, extending from the costal margin to the anal angle, covered with dark brown except the apical area and in several other smaller parts, traversed by a large curved brown strigiform spot which is strangulated below the middle; a round white spot at the cell-end with a black dot in it, and a quadrangular dark submedian spot in the basal third. Hindwing without the blue reflection. 7 and 8 of forewing separated, arising from the areole, 9 and 10 together from its apex, 11 from the basal third. Only the ♀ is known. From Brazil.
- ardosiata*. **C. ardosiata** Dgn. (167 g). Forewing dark violettish grey, lighter in the ♀, coarsely striated darker; a diminutive white brightening before the marginal spot, the spot itself dull yellow, strewn with brown with an irregular brown marking at the interior edge and a small isolated spot beside it; it extends from the costal margin to the anal angle. Hindwing dark. Veins 7 and 8 of forewing separately from the areole, 9 and 10 on a short stalk in one specimen, arising together in another one. French Guiana.
- orima*. **C. orima** Drc. (= *stoica* Dgn.) (169 i). Forewing dark grey, finely striated blackish, an extensive white area before the large straw-coloured marginal spot; the spot itself is black at the costal margin and anal angle and contains 2 large roundish black spots slightly projecting outwards, the lower one extending to the margin. Veins 7 and 8 of forewing on a long stalk from the areole, 9 and 10 together from its apex, and 11 from the basal third; one specimen shows the stalk of 7 and 8 shorter. Brazil, Bolivia, Peru.
- magna*. **C. magna** Schs. (181 f). Dark grey, intensely speckled whitish, with an extensive light, though not contrasting area before the marginal spot; the latter is dull ochreous, with an angled brown marking inside and an ochreous crescent before it, from which streaks proceed above and below, the upper one angular, the lower one extending to the margin; costal margin, anal angle and fringe brown. Hindwing dark. Veins 7 and 8 of forewing distantly separated from the areole, 9 and 10 on a short stalk from its apex, 11 from the centre. Only 1 ♀ known from British Guiana.
- magnifica*. **C. magnifica** Stkr. (= *norax* Drc.) (181 a) is very similar to *magna*, but it is much smaller, the white areas on the forewing clear and distinct, especially that before the marginal spot; the latter is somewhat lighter yellow than in *magna*, the upper end of the dark marking not angled and the two horns of the crescent often reach the margin. Veins 7 and 8 of the forewing arise on a long stalk from the areole, 9 and 10 likewise stalked, but the stalk only half as long, 11 from the centre of the areole. Florida, Mexico, Guatemala. The larva is said to bore in the trunks of oak and hickory.
- omaia*. **C. omaia** Schs. (167 h). Forewing long and narrow, pointed. Forewing dark red-brown with a small subbasal black transverse streak in the middle; the lighter parts yellowish like the marginal spot, especially a round spot at the cell-end and before the marginal spot; the latter contains an irregular brown basal line, streaks at the costal margin and anal angle and two large irregular central spots, the lower one extending to the margin. Veins 7 and 8 of forewing arise separated and parallel, 9 and 10 together from the apex of the areole, 11 from its centre. Only the ♂ is known. From British Guiana.
- arpi*. **C. arpi** Schs. (= *nigripuncta* Dgn.) (167 h). Forewing narrow and pointed in the ♂, less in the ♀. Light grey, speckled white, with a large subbasal quadrangular black spot. Marginal area dull brownish yellow and greyish, the fringe dark, but not so contrasting as usual, the costal-marginal and anal-angular spots and the central marking dark velvety brown, variable, mostly quadrangularly lobate, the lower angle extending to the margin. 7 and 8 of forewing separated, 9 and 10 together. From Guatemala, Costa Rica, Panama, Colombia and Guiana.
- oletta*. **C. oletta** sp. n. (167 h). Forewing of ♂ narrow and pointed, dark grey with black transverse striae and lines, a whitish quadrangular spot submedianly in the discal area, and a slight brightening before the marginal spot; the striae form a straight black line in the basal third, and a more irregular one before the marginal spot; the spot itself is light yellow, the fringe dotted brown, the costal-marginal and anal streaks brown, in the middle with a brown strigiform spot which despatches below a strong arm to the margin. Hindwing dark brown. Veins 7 and 8 of forewing arise separately and parallel from the areole, 9 and 10 together from its apex, 11 before its centre. Medina (Eastern Colombia), 500 m; type in the U. S. National Museum (A. H. FASSL leg., Coll. DOGNIN).
- gaudeator*. **C. gaudeator** Schs. (182 g) is very similar to *magna* (181 f), the ♀ of which has bipectinated antennae (♂ unknown), while the antennae of *gaudeator*-♂ (♀ unknown) are singly pectinated outside, though there are very distinct short double pectinations at the base. The markings are different: while *magna* shows the brown

colour in the marginal spot separated from the inner margin by a narrow yellow line, the brown marking proceeds here to the centre of the yellowish brown marginal area. Veins 7 and 8 distantly separated and parallel, 9 and 10 on a long stalk, and 11 arises from the basal third of the areole. Costa Rica.

C. cossuloides Schs. (182 g) is very similar to *magnifica* in its size and colouring, but the antennae exhibit a series of long pectinations and a series of short angular serrations, while those of *magnifica* are uniformly bipectinated. Forewing more smoothly scaled grey, less speckled, the brown in the marginal spot strangulated or divided into two spots, the lower one of which reaches the margin. Veins 7 and 8 of forewing distantly separated and parallel from the areole, 9 and 10 together from its apex, 11 from the basal third. Guiana and Venezuela.

C. albimacula Dgn. (167 h). Forewing shaded with dark brown at the costal and inner margins, a white spot at the cell-end, from which a broad ray extends, widening in the middle and pointed at the end; central area of forewing mixed with dark yellow and striated dark. Marginal area light yellow with brown spots at the margin, a large one at the anal angle, and a rather small one in the middle, the lower angle of which reaches the margin. Hindwing dark brown. Vein 7 of forewing from the discal cell, 8 from the areole, 9 and 10 separately from its apex, and 11 from the basal third. I only know the ♂ type. Bolivia.

C. tacita Drc. (167 h). The species is not at hand, but DRUCE's figure seems to be clear. I presume the antennae to be singly pectinated. The specimen figured may be a ♀. The whole wing is suffused with dark yellow with a faint brown discal shadow and dark striae, the marginal area of the ground-colour, speckled with white; a dull red band extends down from the apex, getting narrower below, a triangular brown spot before it. Honduras.

C. salara Drc. (= *corita* Schs.) (169 i) is bright grey with a whitish tinge, more or less shaded dark at the costal and inner margins, traversed by dark strigiform lines; a dark submedian spot in the middle area of the wing; a dark grey marginal marking apically, a narrow black arcuate streak before it, more or less connected with the costal margin and distal margin by reticular markings; a narrow dark grey band at the margin, with reticular marking before it. Hindwing almost white with but narrow marginal markings. Vein 7 of forewing from the discal cell, 8 from the areole, 9 and 10 separately from its apex, and 11 from the basal third. Colombia.

C. interrogationis sp. n. Light grey, striated dark, and darker grey at the costal and inner margins; the middle area with a large round brownish black submedian spot, parted brown along vein 1 b; the apical marginal spot dark grey, a thick bent black marking before it, with a round dot below it, like a large interrogation mark on the left wing, reversely on the right wing; the narrow marginal line dark grey, an irregularly dentate blackish brown line before it. Vein 7 on the forewing continues the lower edge of the areole, 8 above it, 9 and 10 on a very short stalk, 11 from the centre of the areole. Merida (Venezuela); the type, 1 ♂, not well preserved, in the U. S. National Museum.

C. arpiodes Dgn. (169 i). Forewing brownish grey, speckled white, one speckle forming a round discal spot, all traversed by blackish striae; a large dark brown spot in the base of the cell and in the basal third of the submedian area, a submedian double spot in the distal third; the apical marginal marking is uniformly dark brown, an anal spot below it. Hindwing dark brown. Vein 7 of forewing from the discal cell, or 7 and 8 from the areole, 9 and 10 on a short stalk from its apex, and 11 before its middle. Two ♂♂ before me, DOGNIN's type and co-type, badly preserved, the apex of the wing in the type severely frayed. Very similar to *C. arpi* Schs., whence it evidently derives its name, but the antennae are only singly pectinated. Brazil (Amazon District).

C. duplex sp. n. (182 g). A well preserved single ♀ from BUSCK's collections in Panama is before me. I can in no way distinguish it from *arpiodes*, except that the outer pair of submedian spots are lighter and more with a leaden gloss than the interior spots; that may also be the case in *arpiodes*, but owing to the bad preservation of the types it cannot be decided; in any case, however, *duplex* seems to me to be much too small as *arpiodes*-♀ and may therefore be better separately named for the present. Cabima (Panama), type in the U. S. National Museum, taken in May.

C. cleptes Dyar (169 i) resembles *arpiodes* and *duplex* (182 g), but it is much smaller, more smoothly grey, without white speckles, the dark spots reduced to blurred shades. Veins 7 and 8 of forewing from the areole, 9 from its apex, 10 from the upper exterior third, and 11 from the basal third, all the veins as far as the apex free. The only ♂ type is before me. British Guiana.

C. tapajoza sp. n. (167 h). Larger than *cleptes*, without the dark anal spot, no white arcuate streak before the black apical area; forewing light grey, striated black with a dark shadowy spot in the submedian distal third. All the veins on the forewing separated, 10 less conspicuous at the apex of the areole than in *cleptes*. Amazons, Rio Tapajoz; type 1 ♂ in the U. S. National Museum.

- elegans*. **C. elegans** Schs. (167 h). Small, light grey with a brownish black costal-marginal border, the inner-marginal part shaded with brownish, the wing more dotted than striated; marginal marking blackish brown, the lower part with a circular bluish-white intermixture with a black central dot, which when the wings are closed must look like a pair of false eyes. Veins 7 and 8 of forewing separated, 9 and 10 on a short stalk, 11 from the middle of the areole. 2 ♂♂ are before me. Brazil: Castro (Parana) and São Paulo.
- striolata*. **C. striolata** Schs. (169 i). A small species, only 1 ♀, light grey, almost white, but the specimen appears to be faded; a black marking in the centre of the costal margin, a double brown submedian spot in the median area; a large brown spot fills the apex more or less, and another spot is in the middle of the distal margin; wings scantily dotted brown. Hindwing brown, white along the costal margin. Vein 7 of forewing from the discal cell, 8 from the areole, 9 and 10 separated from its apex, 11 from the middle, all the veins free. (Brazil (São Paulo).
- marmorata*. **C. marmorata** Schs. (167 h). Forewing yellowish, with a slight golden gloss, many small dark brown spots along the costal margin and on both sides of the median vein, the latter ones roundish extending to $\frac{2}{3}$ of the wing; apex with a slight brassy gloss, with 3 light brown bands. Hindwing light brown. Forewing: vein 7 from the discal cell, 8 from the areole, 9 and 10 from its apex, and 11 from before the middle, all the veins free. French Guiana.
- manes*. **C. manes** Drc. (167 h) is not at hand, DRUCE's figure shows a larger form allied with *marmorata*, without spots, all the markings composed of transverse striae, the apex similar. Panama.
- niveogrisea*. **C. niveogrisea** Schs. (183 a). Thorax and the outermost base of the forewing white; forewing dark grey, indistinctly striated, a few accumulated white dots in the discal area and along the costal margin; marginal area yellowish white, enclosing a brown more or less interrupted bow, the yellow before it somewhat darkened. Hindwing yellowish white or blackish. Vein 7 of forewing from the discal cell, 8 from the areole, 9 and 10 on a short stalk from its apex, 11 from the basal third. I have not seen any ♀. Guiana, Venezuela, and Costa Rica.
- nigripennata*. **C. nigripennata** Dgn. (183 a). Thorax and base of forewing white. Forewing smoothly scaled grey, distinctly reticulated darker; marginal spot yellow with a coherent brownish black arcuate margin, a yellow stripe at the apex and a black patch above it. Forewing: 7 and 8 from the areole, 9 and 10 on a short stalk, 11 from the basal third. Hindwing blackish. Both sexes before me. Panama; French Guiana; Brazil (Amazons).
- notodontoides*. **C. notodontoides** Schs. (181 g). Forewing narrow, with parallel margins, pointed in the ♂; thorax white, also the base of the forewing in the ♀, not so in the ♂; the centre of the forewing yellowish white, basally shaded with brown, also behind the centre, passing over into black, the marginal area reticularly dotted on the yellowish white ground. Hindwing of ♂ tinged white with dark veins, of ♀ dusted brown on the yellowish ground. Veins 7 and 8 from the areole, 9 and 10 on a moderately long stalk, 11 from the basal third of the areole. Brazil (Rio de Janeiro and Joinville).
- philobia*. **C. philobia** Drc. (181 g). Forewing dingy white, tinged with yellow along the costal margin, slightly speckled; 3 large grey spots in the median area, and 2 large round brownish black coherent spots obliquely below the apex. Veins 7—11 of forewing from the areole, 9 and 10 together from the apex, 11 from the basal third. Mexico, Panama, Ecuador (Zaruma).
- praeclara*. **C. praeclara** Schs. (= ockendeni Drc.) (181 g). Forewing dingy white with brown transverse striae and 3 or 4 broad irregular leaden glossy stripes; 2 large round brown spots in the marginal area are sometimes confluent (*ockendeni*). Veins 7—10 of forewing separately from the areole, only in one specimen 8 and 9 together. The ♀ is not at hand. Brazil, Bolivia.
- bistellata*. **C. bistellata** Dgn. Only doubtfully different from *praeclara*, the lead-coloured bands are narrower and of a less intense leaden gloss, less contrasting, the marginal spots browner, the neurulation the same. Both sexes of this form at hand. French Guiana.
- alfarae*. **C. alfarae** Schs. (183 a). Forewing dingy white, densely striated brown and occasionally with small spots of a bronze gloss, a round spot before the apex, one below it is not rounded, but variable, distorted; more or less distinct spots also along the submedian area. Forewing: vein 7 from the areole, 8 and 9 on a rather long stalk, 10 and 11 from the apex of the areole; ♀ not at hand. Guatemala; Costa Rica; Panama.
- rotundopuncta*. **C. rotundopuncta** Schs. (183 a). A small species, suffused with reddish brown except the anal area, a small round brown spot before the apex; the submedian area shows reddish spots in the middle and one spot at the inner margin. Forewing: 7—10 from the areole, 8 and 9 on a rather short long stalk, 7 connected with the base of the stalk; this obliterates the difference between *Trigena* and *Cossula*, but I believe there cannot be any mistaking. Brazil.

C. discopuncta Schs. (183 a). Dingy silvery whitish, 3 brown spots in an oblique row in the centre of the wing, the discal one large, the others small; faint grey speckles are condensed at the distal margin and anal angle, forming a border and a streak above the anal angle. Hindwing white. Forewing with veins 7 to 11 from the areole, 7 and 8 nearing each other at the base, 9 and 10 together. ♀ unknown. Brazil (São Paulo).

C. rille sp. n. (183 b). Like *discopuncta*, but the spots are smaller, the middle one extinct; anal angle and margin as far as the apex with a broad area of grey striation. Neuration as in *discopuncta*, but 7 and 8 more separated. Brazil (Rio de Janeiro and Novo Friburgo); type in the U. S. National Museum.

C. ryssa sp. n. (183 b). Forewing whitish grey, with brown transverse striae which are more densely arranged in the exterior half of the wing; a narrow brown shadow along the costal margin and broadly across the anal angle almost to the base, 3 round brownish black spots in the middle, the discal one the largest. Forewing with veins 7—11 from the areole, all free, 9—10 nearing each other or together. Bolivia (Rio Songo); Carabaya (Peru); type in the U. S. National Museum.

C. maruga Schs. (181 g). Like *ryssa*, but the stripes in the distal half of the wing much more intense, the violettish grey bands intermixed with orange brown, producing an iridescent impression; the 3 discal dots doubled by smaller ones outside. Veins 7—11 of forewing arise freely from the areole. ♀ not known. Brazil (Castro, Novo Friburgo, Joinville, São Paulo); Dutch Guiana (Geldersland).

C. centrosema sp. n. (183 b). Forewing broader and more quadrangular than in *maruga*; yellowish white, forewing feebly tinged with brown, densely striated dark brown, connected by brown shading in the centre of the distal half, a large irregularly rounded velvety black discal spot before it. Veins 7—11 of forewing from the areole, free, 9 and 10 also separated. Hindwing without markings. From Colombia (Buena Vista); type in the U. S. National Museum.

C. julius Schs. (181 h). Dingy white, apex of forewing very pointed, longitudinally shaded with brown, hardly reticulated or striated; darker shaded along the inner and outer margins, inside of it a parallel shadow to the apex and a short stripe above it, bordering on a double white stripe to the apex; the disc with a large irregularly round dark brown spot, double and tinged with black downward. Forewing with veins 7—10 from the areole, 9 and 10 connected. Only the ♂ type is known. Brazil, Novo Friburgo.

C. acutipennis Schs. (183 b). Smaller and with less pointed wings than *julius*. The distal half of the wing is filled with olive shading and spots, traversed by the double white apical stripe, the discal spot smaller and extinct, more olive brown, with a doubling below it and a third spot at the inner margin. The ♀ is larger, the hindwing tinged with black, forewing scarcely pointed, the white apical stripe present, but more bent. Forewing dingy white, feebly speckled; distal and inner margins above the anal angle crossed by brown and reddish shadowy bands; the discal spot round, very large, velvety dark brown. Forewing with veins 7—11 from the areole, 9 and 10 more or less distinctly connected. French Guiana and Bolivia (Rio Songo).

C. cor-regis sp. n. (183 b). Thorax yellowish brown in front, white behind. Forewing dingy white, tinged with dark yellow in the cell, the lower half of the inner margin, and especially below the apex; a white stripe extends through the centre of the wing to the apex; anal area intensely speckled purple brown, filled with white in the middle; the small irregular discal spot is situate in dark clouds; a small dark spot near the inner margin inwardly. Veins 7—11 from the areole, 9 and 10 connected. Hindwing dingy white. Brazil (Novo Friburgo); type in the U. S. National Museum.

C. vinnea Schs. (183 b). White, with interrupted brown and black reticular markings forming an oblique shadow above the anal angle; discal spot large, brown, with a small doubling below it. The ♀ is darker, with grey hindwings, the distal third more intensely smoky. Forewing with veins 7—11 from the areole, all separated, or 9 and 10 connected. Guatemala.

9. Genus: **Heterocoma** B. & McD.

Forewing with veins 1 and 1b separated, the discal vein forked, 7—10 from the areole which is only small, 11 from the discal cell near the base. Discal vein of hindwing forked. 6 and 7 well stalked as in *Cossus*, 8 free. Only 1 species:

H. albistriga B. & McD. (181 h) is not at hand, according to the figure it is of a stout structure, with rather obtuse wings; the ground-colour is grey, a white stripe along the costal margin, another stripe along the submedian vein as far as half the length of the wing, finally a short one from the cell-end obliquely to the

anal angle. The ♂ is darker, the light markings contrasting, the ♀ is lighter, the markings not prominent. Arizona (Cochise County).

10. Genus: **Miacora** Dyar.

Veins 1 and 1b of forewing distantly separated, 2—5 arise from the lower cell-angle, discal vein forked; 6 from the cell-apex; areole small, half of its length projecting beyond the discal cell, 7—9 stalked from it, 10 above it, 11 from the discal cell near the base. On the hindwing the cell projects far, the discal vein is not forked, 7 and 8 are separated, but nearing each other. The frenulum is only small in the ♂, or absent altogether.

Type: *M. tropicalis* Schs.

- tropicalis*. **M. tropicalis** Schs. (183 c) is a large whitish grey species with dark shading through the centre, so that more purely whitish areas appear basally and apically, with fine and coarse striated reticular markings; the coarse ones form an X-shaped marking in the marginal area. ♂ antennae plain, flattened. British Guiana (Omai).
- diffidens*. **M. diffidens** Dyar (181 h) is smaller and darker than *tropicalis* with the same formation of the antennae, the two lines in the distal area of the forewing are bent and about parallel, not crossing each other. Mexico (Zacualpan).
- adolescens*. **M. adolescens** Dyar differs from *diffidens* in coarsely and shortly serrated antennae in the ♂. The wing is shaded darker; the distinct black lines in the distal area are separated and almost parallel, distantly remote from each other. Panama (Taboga I.).
- subtropicalis*. **M. subtropicalis** sp. n. (183 c). As in the following species, the ♂ has here bipectinate antennae. Dark grey, reticularly striated with fine and coarse black lines; a distinct line from the exterior third of the costal-margin to the lower third of the distal margin; right behind the middle two lines form an X-shaped marking extending from the costal margin to the inner margin. Hindwing grey. San Salvador, Guatemala; type in the U. S. National Museum.
- perplexa*. **M. perplexa** Neum. & Dyar (181 i) is not at hand, but the figures of BARNES & MCD. are excellent. Forewing grey with a silky gloss, very finely reticulated, a Y-shaped forked line almost in the middle, another one in the distal area. Hindwing monotonously light grey with a silky gloss. Colorado and Arizona.
- leucegchytes*. **M. leucegchytes** Dyar (183 c) is smaller than *perplexa*, the striation still finer, the dark exterior lines differently placed. Mexico (S. Luis Potosi).
- luzena*. **M. luzena** Barnes (181 b). A smaller species, marked like *leucegchyta*, but the striation coarser. Only ♀♀ known. The formation of the ♂ antennae therefore does not allow for the present to fix the position definitely. Arizona (Cochise Co.).

11. Genus: **Psychopsis** gen. nov.

A small species with triangular wings. Forewing with veins 1 and 1b separated, 2—5 arise from the lower cell-angle; discal vein forked; 6 from the upper cell-angle; 7—9 stalked from the end of the small areole, 10 from it and 11 far back from the discal cell. Cell of hindwing very long, especially the lower angle far produced, veins 3—5 short, the discal vein shortly forked; 6 and 7 separated, but very close together from the upper cell-angle, 8 free. Antennae of ♂ bipectinate, the ♂ with a slender, rather long frenulum-thorn. Only 1 species.

- infantilis*. **C. infantilis** Schs. (182 g). Small, black, resembling a Psychid; forewing clouded somewhat lighter and with indistinct fine and coarse linear striae, the coarse ones forming an irregularly forked line in the marginal area. Only 1 ♂ known. Costa Rica.

12. Genus: **Chilecomadia** gen. nov.

Veins 1 and 1b of forewing separated, the cell uniformly rounded, veins 2—6 arising at equal distances, the discal vein long forked; veins 7—10 from the small areole, 7 and 8 on a short stalk, 11 from the centre of the discal cell. Hindwing likewise with a rounded cell, veins 2—7 all separated and at equal distances, 8 free; discal vein forked. Antennae of ♂ serrated on one side. ♂ with a long thick frenulum.

Type: *Ch. moorei* Silva Figueroa.

- moorei*. **Ch. moorei** Silva Figueroa (183 c). Light grey, the disc often tinged with greenish, with fine lines and large coarse dark striae. Hindwing light grey, interruptedly reticulated. Both sexes similar. Chile. Bred by Dr. SILVA in great numbers from trunks of willows, a large series from this breeding in the National Museum at Washington.

Ch. valdiviana Phil. is at once discernible from *moorei* in both sexes by the black hindwings. Forewing *valdiviana*, more pointed likewise in both sexes. Forewing of ♂ profusely dusted black, that of the ♀ more resembling the forewing of *moorei* and only shaded blackish in the median area. Chile. The larva likewise bores into willows.

13. Genus: **Hypopta** Hbn.

Veins 1 and 1b of forewing separated, the discal veins forked on both wings. Veins 7 + 9 of forewing stalked from the small areole, 10 from it, 11 remote from it from the discal cell. The cell on the hindwing is projecting, veins 5—7 arise from the same base, 8 free.

Type: *H. caestrum* Hbn.

H. nana Stkr. (181 c). The small grey species resembles a tiny *Cossus cossus*, shaded somewhat lighter *nana*, and darker and reticulated with black lines, especially in the disc and marginal area, 2 lines being particularly prominent, the interior one forked in the middle, a whitish spot in the triangular area formed thereby, the exterior line likewise forked, but only shortly below the apex; another whitish spot in the interior lower half of the median area. Only the ♀ is known. Texas.

H. nina Schs. (183 c) has narrower wings and a very long abdomen; forewing simply grey with scanty *nina*, black striae. The frenulum in the ♂ is a long slender spine extending into a reverted fold of the subcosta of the forewing. Costa Rica.

H. connecta B. & McD. (181 i), described as *Acossus*, is presumably better ranged here; it recalls *nana*. *connecta*. Thorax light brownish, forewing smoky brown in the basal half, lighter outside and dusted with silvery white; the black transverse striation forms two lines connected by a thicker longitudinal streak on the submedian half, the outer one bifurcating near the costal margin; faint reticular markings along the distal margin. Hindwing lighter, only with traces of reticular markings. Texas (San Benito).

H. redtenbacheri Hammerschmidt (= agavis Blasq. chilodora Dyar) (181 i). Forewing grey in different *redtenbacheri* shades, the striae marked by shades; costal margin rather broadly white, or at least striped whitish on two thirds; whitish scales bordered by black ones form 2 raised-looking transverse lines which may be increased to 4. Hindwing generally dark grey. Antennae of ♂ bipectinate, of ♀ plain. ♂ frenulum as in *nina*. Mexico. The larva lives in the trunks of Agavae.

H. engelhardtii B. & Benj. This species and the following ones have been ranged in the genus *Comadia engelhardtii* by their authors, but they belong to this genus here. Forewing whitish, strewn with black with a faded brownish shading below it, with a black median vein, the cell also often scaled black. Hindwing light, sometimes dusted blackish brown. Thorax broadly scaled. Expanse of wings: 31—34 mm. Utah.

H. dolli B. & Benj. shows the thorax more covered with hair-shaped scales, like the following species, *dolli*, too. Ground-colour of forewing yellowish white, strewn with blackish scales forming reticular markings; the veins indistinctly marked black, especially at the lower discocellular vein; the reticular markings may become very distinct, but they may also disappear nearly altogether. Hindwing grey. Expanse of wings: 28—35 mm. Nevada; Utah.

H. subterminata B. & Benj. Forewing white, so densely scaled black that it appears dark grey, some *subterminata* of the scales being confluent and forming reticular markings; a feeble band is formed subterminally in some specimens; the transverse vein is usually strongly scaled black. Hindwing blackish brown. Expanse of wings: 37—49 mm. Arizona (Redington).

H. stabilis B. & Benj. Ground-colour of forewing light, so much darkened by scattered black scales *stabilis*, that it appears grey; veins, especially the median vein, blackish, particularly at the lower discocellular vein, the subcostal area somewhat lighter than the rest of the wing. Hindwing dull blackish brown with darker veins. Expanse of wings: 35—37 mm. Utah.

H. bertholdi Grt. (182 a). Silvery grey, shaded blackish brown with a blackish basal streak below the *bertholdi*, subcosta, the median vein also narrowly blackish, farther outside faded between the cell-branches. Fringe speckled dark. Hindwing grey. Colouring and marking most variable. Colorado, New Mexico, Utah, California, Arizona. — **fusca** B. & Benj. is a form more intensely dusted brownish black, the marking also darker, *fusca*, Colorado.

H. edwardi Neum. & Dyar (= *edwardsi* Dalla Torre) may be merely a form of *bertholdi*. Body black, *edwardi*, antennae white with black pectinations. Forewing white, strewn with black, most densely so in the apical part and below the median vein and vein 2, whereas the cell remains lightest; some brownish faded shading between the bases of the veins 2—5. Hindwing brownish grey, fringe as on forewing white with brown ends. Expanse of wings: 40 mm. Only the type, 1 ♂ from Colorado, is known.

- intrusa*. **H. intrusa** B. & Benj. is so very closely allied to *bertholdi* that it is only comparatively to be separated. It is somewhat larger, with a stronger body, the dark dusting between the median branches more distinct, brownish, forming a dark roundish spot between 2 and 3. Hindwing brown. Expanse of wings: 37—47 mm. South California. The larva lives in the trunk and roots of Lupinae.
- manfredi*. **H. manfredi** Neum. (182 a) is the smallest and lightest species. Body and forewing including fringe yellowish white, with tiny light brownish speckles and a discal blotch of the same colour. Hindwing monotonous, somewhat darker. Expanse of wings: 30 mm. Arizona.
- henrici*. **H. henrici** Grt. (182 a) is as large as *bertholdi* which it also resembles somewhat, though it is more interrupted by white, the costal margin broadly silvery white like the median vein, too, the rest of the wing brownish, slightly dusted over with ochre. Hindwing dark blackish brown in the ♀, lighter in the ♂. Arizona.

14. Genus: **Pernambis** Schs.

Forewing without the areole, the discal vein with a long fork, the veins 1 and 1b separated; vein 2—11 from the cell, 4 and 5 arising together, 6 and 7 on a short stalk. Discal vein of hindwing forked, veins 3 + 4 together from the sharp lower cell-angle, the cell itself angularly bent inward; 6 and 7 separated with an oblique connecting bar far outside; 8 free. Antennae of ♂ bipectinate, of ♀ flattened laminate.

Type: *P. intervenata* Schs.

- intervenata*. **P. intervenata** Schs. (183 d). Forewing dark mouse-coloured grey, all the veins broadly striped white. Described from a single ♀ which is much damaged. Brazil (Pernambuco).
- fuscescens*. **P. fuscescens** Dgn. (183 d). Forewing dark mouse-coloured brown, all the veins narrowly striped white, only the median vein somewhat more broadly striped. According to a single ♂ from Argentina.
- albescens*. **P. albescens** Dgn. (183 d). Forewing grey, all the veins broadly striped white, subcostally flown together and forming a broader stripe. Hindwing white with grey internerval spots at the margin. Only 2 ♀♀ known, one from Venezuela, the habitat of the type not known.

15. Genus: **Acosus** Dyar.

Veins 1 and 1b of forewing separated, discal vein forked on both wings, areole narrow, projecting beyond the discal cell, 7—9 from the apex, 10 before it and 11 more remote from the discal cell. Cell of hindwing entering with a flat angle; 6 and 7 stalked; the upper edge of the cell projecting angularly with a bar to vein 8.

Type: *A. undosus* Lint.

- undosus*. **A. undosus** Lint. (= *brucei* French) (182 b). Collar ochreous, thorax grey; the white ground of the forewing finely transversely striated black with 2 thicker lines through the middle and before the distal margin. Abdomen and hindwing light grey, the latter less striated. Colorado; Wyoming. Larva probably in poplars.
- centerensis*. **A. centerensis** Lint. (182 b) is well distinguished by the very scantily scaled hindwings with black fringes and a blackish-haired basal part of the inner margin. Distal part of forewing likewise more scantily scaled, the basal part more densely scaled black, everywhere finely transversely striated, often connected into fine lines. Northern States, to the west as far as British Columbia. The larva lives in poplars.
- populi*. **A. populi** Wkr. (182 b) differs from *undosus* in the absence of the thicker transverse lines; forewing very light ash-grey, very finely transversely striated and reticulated. Hindwing even much lighter and scarcely striated. North-Western North America. — **generosus** Dyar is more or less shaded black, a much darker form from the Northern Rocky Mountains. — **angrezi** Bailey is another form, perhaps also a distinct species, with a black thorax and yellowish grey collar, the forewing more irregularly shaded black, for instance in the apical and marginal thirds, inwardly widened obliquely downward, with longer internerval streaks before the margin.
- ore*. Hindwing yellowish grey. Nevada. — **ore** Stkr. (182 b) which many consider to be a distinct species, is again a lighter form, but not so light as *populi* and densely and irregularly mixed with dark. Colorado. The larva lives in poplars.

16. Genus: **Prionoxystus** Grt.

Sexes dissimilar; antennae pectinate in both sexes. Thorax covered with flat scales. Distal margin of hindwing concave in the ♂, rounded in the ♀. Neuration as in *Acosus*.

Type: *P. robiniae* Peck.

P. robiniae Peck (= *crepera* Harr., *plagiatus* Wkr.) (182 c). A most variable species as regards the *robiniae*. markings. Forewing grey, reticulated black and irregularly spotted blackish. Hindwing of ♂ ochreous, basal area, costal margin and a narrow marginal line black, grey in the ♀. Distributed all over the United States. Larva in different trees. — **reticulatus** Lint. (= *querciperda* Pack.) has more diaphanous wings, especially in *reticulatus* the distal third, less distinctly reticulated, without any dark spots. Hindwing monotonously smoky brown, scarcely reticulated. An aberrative ♀ form. — **quercus** Ehrm. is likewise an aberrative ♀ form with yellow hind- *quercus*. wings like the ♂. — **mixtus** B. & Benj. is a race with lighter forewings and hindwings, the ♂ with much reduced *mixtus*. black on the hindwing. Colorado. — **subnigrus** B. & Benj. is darker, the hindwing of the ♀ with a faint yellow- *subnigrus*. ish tint. The south-western race from Arizona. — **flavotinctus** B. & Benj. is as light as *mixtus*, the black of *flavotinctus*. the ♂ hindwing somewhat more increased, with a rounder interior angle, the ♀ hindwing of a distinct yellow tint, without attaining the aberration *quercus*. California. — **zabolicus** Stkr. is a ♀ form with more intensely *zabolicus*. blackened hindwings, from Florida.

P. macmurtrei Guer. (= *querciperda* Fitch.) (182 c). ♂ very small with almost hyaline forewings, with *macmurtrei*. black transverse striations, blackened at the inner margin in the basal two thirds like the hindwing. ♀ much larger, likewise very scantily scaled, with fine and extensive transverse striations, a somewhat more coherent line from the exterior two thirds of the costal margin to the anal angle. Atlantic States to the west as far as Minnesota.

17. Genus: **Givira** Wkr.

Anal veins of forewing united; 6 and 7 of hindwing arising from the same base or stalked; discal veins forked in both wings. Antennae of ♂ shortly bipectinated, of ♀ plain or serrate. One of the largest Cossid genera.

Type: *tristis* Wkr.

Section I. Hindwing with a cross-vein between 7 and 8 (*Givira* Wkr.).

G. quadra Schs. (= *gnoma* Schs.) (182 d). Grey, brightened with whitish or reddish flesh-colour; a *quadra*. round dark punctiform spot at the cell-end and a larger spot basally above the interior margin below the median vein. Brazilian specimens are mixed with dull reddish flesh-colour, northern ones almost white in the middle, but the types of the two names are from Brazil; I avoid, however, using a new name. Brazil; Panama; Costa Rica.

G. superquadra Dgn. (183 d) is somewhat larger than *quadra*, and more marked; the dark basal spot is *superquadra*. incised on both sides by a reddish area which is connected by a light line; the discal spot is larger and more quadrangular, with dark shading behind it and below it. French Guiana.

G. argenteolaminata Dgn. (183 d) is a still more variegated species of the *quadra*-type. Dark brown, *argenteo-* *taminata*. the dark basal spot more divided into roundish spots and filled with a large quadrangular silvery spot; a dark shadow behind the large discal dot as far as the margin, which is strewn with blue scales and contains a series of larger brown spots. Only the type is known. French Guiana.

G. binubila Dgn. (183 e). The brown basal spot is divided into single badly defined speckles; the cell is *binubila*. striated brown, the area between veins 2 and 3 lighter and not marked. Hindwing brownish black. Only the type is badly preserved. French Guiana.

G. aroa Schs. (182 d). Forewing covered with large, velvety dark brown spots which, however, do *aroa*. not contrast much with the lighter, less velvety ground; a larger submarginal spot is above veins 2 and 3, others however, are similarly conspicuous. Hindwing blackish brown. Mexico; Central America; Venezuela; French Guiana; Bolivia.

G. juturna Schs. (182 d) is very similar to *aroa*, but there is a dark spot in the light area below vein 2 *juturna*. in the submedian area, so that the light area does not reach the cell, which is the case in *aroa*. Hindwing whitish, more or less speckled. Mexico; Costa Rica; Panama; Brazil.

G. obidosa Dgn. (183 e). Here the spots are angular on a more lilac grey ground, with an oblique whitish *obidosa*. subbasal line, another line from the costal margin bent on vein 3 to the distal margin, and an oval oblique discal ring. Hindwing whitish, feebly reticulated violettish grey. Only the type is known from the Amazons (Obidos).

G. amanosa Schs. (183 e) generally resembles *obidosa*, but with reverse colours, the dark spots angular, *amanosa*. the lighter interspaces rounded. Costa Rica.

G. egipan Dgn. (183 e). Distal half of forewing light, large dark speckles on the light brown ground *egipan*. only along the costal margin, basally and at the interior edge of the fringe. Hindwing without markings. Only the type is known. A large species from Brazil.

G. tigrata Schs. (183 e). Brownish yellow with a silver reflection, the markings richly red-brown; thorax *tigrata*.

and abdomen equally coloured; the forewing with rows of dark brown spots. Hindwing light, slightly speckled. Only 2 ♂♂ known. Costa Rica.

- rufiflava*. **G. rufiflava** Dgn. is not so bright yellow as *tigrata*, the whole apical part of the forewing broadly suffused with dark brown, without a darker median band. Only 1 badly preserved ♂ specimen. French Guiana.
- invenusta*. **G. invenusta** Schs. (183 e) is a larger species; of a reddish brown flesh colour, shaded with velvety blackish; subbasal line shaded darker along the submedian line outward; a blackish shadow from the cell-end to the anal angle, a triple stripe at the apex. Hindwing of ♂ triangular, of ♀ rounded, black, deeper black in the ♂. Veins 6 and 7 of hindwing only on a very short stalk, and perhaps the species would be better ranged among *Langsdorfia*. Brazil.
- triplex*. **G. triplex** Schs. (183 f). Grey with many angular brown spots intermixed with a bright yellowish brown colour; 3—5 black internerval stripes, the veins themselves reddish; apex and anal angle as far as vein 2 broadly light. French Guiana and Amazons. Brazilian specimens differ in the black stripe being only present between 3 and 4, and the dark spots at the cell-end being rounded and more concentrated. Taperinha.
- sabulosa*. **G. sabulosa** Schs. (182 d). Brown, somewhat yellowish, densely reticulated forming spots, the only real markings being submarginal interrupted reticulations; the lighter parts are incompletely rounded spots with darker ones between them. Hindwing dark. Brazil.
- sterila*. **G. sterila** Dgn. (183 f). Grey with faint fine darker reticular markings and a black irregular oblique line from the costal margin near the base outward to vein 1, coarse reticular marking across the apex. Hindwing likewise well reticulated. French Guiana. A doubtless *Langsdorfia*.
- fidelis*. **G. fidelis** Schs. (183 f). Dark red-brown, quite indistinctly reticulated black, mixed with reddish flesh-colour at the costal margin; a strong black streak along the inner margin for $\frac{2}{3}$; margin somewhat lighter, with a reticulated submarginal parallel line. Guatemala, Costa Rica, and Peru.
- clathrata*. **G. clathrata** Dgn. (183 f). Of a warm dark brown with fine extinct reticular markings and coarser black striae, the latter forming irregular transverse lines submarginally and in the basal third, connected by a line along vein 1. Only 2 ♀♀ at hand, veins 6 and 7 of hindwing on a very short stalk or quite separated. French Guiana. Probably a *Langsdorfia*.
- morosa*. **G. morosa** Schs. (183 f). A dark brown species with uniformly fine reticular markings, without coarse lines. Of a warm dark brown colour, not scantily scaled, the reticular markings dense; only an extinct darker antemedian line extends obliquely from the inner margin outward to the costal margin. Costa Rica and Bolivia (Rio Songo).
- mucida*. **G. mucida** H. Edw. (182 e). Forewing greyish brown, rather feebly striated and partly confluent to reticular markings, finely dusted darker grey, but an area in and below the cell remains lighter, whitish; a dark diffuse spot at the cell-end; fringe speckled brown and white. Hindwing dingy whitish, speckled with brown. Arizona.
- guata*. **G. guata** Schs. (183 f). Forewing light reddish brown with a lilac tinge, a dark shadow from the centre of the costal margin to the anal angle comprises the apex; the striae are chiefly transverse, dark brown, blurred; more reticular on the lighter hindwing. Guatemala.
- tecnessa*. **G. tecnessa** Schs. (183 g). Dark red-brown, the forewing with broad bands of transverse spot-like striae, especially prominent an undulated transverse dark shadowy line. Hindwing lighter except the submarginal area. Only the single type is known, from Brazil.
- difflua*. **G. difflua** Dgn. (183 g) resembles the following *arbeloides*, but it is somewhat more yellowish, and the macular markings of the forewing form a broad subterminal band in the distal third of the wing. Argentina.
- arbeloides*. **G. arbeloides** Dyar (= *flavescens* Dgn., *felicoma* Dyar) (182 e) is yellowish brown, with darker purple brown spot-like speckles, so that rows of spots are formed between the veins, especially along the inner margin, in a broad submarginal area and at the cell-end. The lighter hindwing is feebly speckled darker, with a large dark discal spot. Southern United States (Texas), Mexico and Central America. — **rufescens** B. & McD. shows brighter red-brown spots, so that the insect looks much redder. Described from Missouri (Greenville).
- talboti*. **G. talboti** Dgn. (183 g). Thinly scaled, especially the hindwing diaphanous, the shape of the wings more roundish, pointed at the apex. Ground-colour dusty grey, the reticular markings strigiform, dark carmine, especially at the costal margin, rather uniformly coarse. Hindwing with dark veins and a dark shaded inner margin, with faint red apical reticular markings. Only the type known, from Bolivia.
- rubida*. **G. rubida** Dgn. (183 g) has somewhat more quadrangularly pointed forewings, the hindwing not dia-

phanous. Forewing uniformly dark red-brown, feebly speckled darker, hindwing dingy white, fringe red-brown, and with a red-brown wedge-like spot before the anal angle. French Guiana.

G. tristis *Wkr.* Forewing dull red-brown, with slightly darker spots, hindwing tinged yellow, light or *tristis*, rather dark covered all over with small indistinct spot-like reticular markings. Venezuela.

G. modisma *Schs.* (183 g). Similarly marked as *tristis* and perhaps the same species; but while in *tristis modisma*, the reticular lines in the distal area form separated oblique spots, there are here two lines parallel with the distal margin. The two specimens before me do not differ from each other, but one of them has much darker hindwings. Guatemala.

G. harcour *sp. n.* (183 g) resembles *tristis* and *modisma*, but the wings are narrower and more pointed, *harcour*, the dark red ground with hardly any reticulations, and before the margin there are no linear markings; spotted costal-marginal markings are prominent owing to their being edged with yellowish. Hindwing yellowish, slightly strewn at the distal margin, the margin itself spotted dark brown, and a reddish shadow extends before the inner margin towards the base. 1 ♂ from the Amazons (Teffé), type in the U. S. National Museum.

G. modia *sp. n.* (183 h) has the shape of wings of *arbeloides* which it resembles, but the ground-colour *modia*, is a uniformly soft red-brown; the reticular markings striated or spotted, darker brown, blurred; a darker cloud at the cell-end, and an accumulation of dark scales before the middle of the inner margin, at the same place where there is a feeble discal spot on the hindwing. Hindwing only somewhat lighter than the forewing, otherwise similar. 1 ♂ from the Amazons (Praniha); type in the U. S. National Museum.

Section II. Hindwing without a connecting bar between 7 and 8 (*Lentagenia* Dyar).

G. eureka *Schs.* (183 h) has long wings, with parallel margins and an obtuse apex; forewing light lilac *eureka*, grey, between the base of veins 2 and 1 with a large triangular brown spot edged with whitish, the interspaces of the cell-branches blackish and a bent blackish shadow from above 4 to the apex; a brown area below vein 1 at the inner margin. Only the type, 1 ♂, is known, from Guatemala.

G. guiguasia *Dgn.* (183 h). Forewing grey with linear transverse striae, with a large dark brown spot *guiguasia*, near the base enclosing an oval silvery spot on vein 1, a small brown spot at the cell-end. Hindwing blackish. Only the ♂ type is known, from Venezuela.

G. ornata *Dgn.* (= ? *saladota* *Dgn.*) (183 h) is a very small species with differently arranged markings; *ornata*, white subterminally and above the anal angle on the rusty brown ground, with irregular small brown spots in the subterminal area and with an oblique row of spots through the middle of the cell to before the anal angle. From Argentina. The *saladota*-type is no more recognizable, oily, worn and broken, the size and habitat the same; it may nevertheless be another species.

G. perfida *Schs.* (183 h). Dark brownish, densely speckled and spotted, the spots basally more or less *perfida*, confluent; an angled white-dusted antemedian band and a small spot at the cell-end; the small spots lighter than the ground. Hindwing dark with lighter punctiform spots; fringe white. Guatemala.

G. carisca *Schs.* (183 h) is smaller than *perfida*, the punctiform spots darker than the ground, the yellow- *carisca*, ish white oblique band extends to before the anal angle, the discal spot is rusty brown. Mexico.

G. minuta *B. & McD.* (182 e) is still much smaller than *carisca* which it resembles, though it lacks the *minuta*, light oblique patch to the anal angle. Forewing light ochreous brown, yellowish white at the costal margin, shaded brownish black behind the cell; a smoky brown spot at the base of the costal margin, a larger triangular one behind it, further spots in the centre of the cell and at the end, and a large one above the centre of the inner margin, behind which spots there is white dusting, another white spot in the middle of the distal margin. Hindwing dark smoky brown. Arizona.

G. vassilia *Schs.* (183 i) is a brown species, the body more whitish; the brown spots on the forewing *vassilia*, are large, one near the base, one behind it and 2 subapical ones; veins striped white; vein 2 terminates into the anal angle, a double white stripe below it. Veins 6 and 7 of hindwing stalked, then almost parallel, only slightly separated, as in *Langsdorfia*. Hindwing black with light-edged marginal spots. Guatemala.

G. plagiata *Schs.* (= *daphne* *Drc.*) (182 f). Forewing dark lilac grey, with distinct rounded dark brown *plagiata*, small spots, scantily scattered over the wing, 1 near the base, 2 in the middle, and 3 subapical ones. Hindwing blackish. Mexico; San Salvador; Guatemala; Costa Rica; Panama; Colombia; Venezuela.

G. pulverosa *Hmps.* is very similar to *plagiata*, but all the spots are much smaller, but while in *plagiata pulverosa*, the subapical spots are situate in a straight or slightly concave line, they are in a convex row parallel to the distal margin in *pulverosa*. Lesser Antilles.

G. pardana *Schs.* (183 i) differs from *pulverosa* in larger spots arranged in 3 dense rows. Ground colour *pardana*.

brown, the spots darker brown. Hindwing dark brown, with slightly darker spots. Only the ♂ type from Brazil is known.

- racana.* **G. racana** Dgn. (183 i). Dark grey with distinctly rounded black spots, 5 in a row near the base, 2 larger ones in the subterminal area, and 4 small subapical ones. Veins 6 and 7 of hindwing stalked, then almost parallel as in *Langsdorfia*. Only the ♂ type from Argentina is known.
- tristani.* **G. tristani** Schs. (182 f). Forewing lilac grey, subterminally speckled lighter; a large dark spot in the centre of the inner margin, composed of an upper oblong velvety black spot and a long dark brown shadow below it, the latter traversed by striae. *G. brunnea* Köhler, from Argentina, is probably the same species. Mexico, Guatemala, and Costa Rica, also from the Amazons (Teffé).
- circumpunctata.* **G. circumpunctata** Dgn. (183 i) resembles *plagiata*, but it is much smaller, and the subapical spots are absent; only one spot in the cell. Only the ♀ type from French Guiana is known.
- salome.* **G. salome** Dyar (182 f) looks very much like *tristani*, but the spot above the inner margin is short and triangular and does not extend below vein 1. Mexico.
- gemina.* **G. gemina** Dgn. (183 i). Forewing lilac grey with numerous small dark spots and 2 larger ones above the middle of the inner margin obliquely above each other, separated by the submedian vein. Venezuela.
- invida.* **G. invida** Dgn. (183 i). Delicately lilac grey with small roundish brown spots, a spot above the inner margin and with 2 rather large spots in the otherwise spotless submarginal area, a subapical one, and one in the middle. Hindwing whitish, fringe spotted dark. The only ♂ type from Venezuela is before me.
- invidiosa.* **G. invidiosa** Dgn. (184 a). Forewing lilac grey, differently shaded; a rusty brown area in the centre of the inner margin, and a series of 5 small brown subapical spots. Hindwing grey with dark marginal spots. Brazil (Amazons District). Only the ♀ type is known.
- delicata.* **G. delicata** Schs. resembles *invidiosa*, but it is more delicately grey and without the small subapical spots. Hindwing white with small indistinct dark spots on the fringe. Guatemala; only the ♂ type is known.
- cleopatra.* **G. cleopatra** B. & McD. Dark grey, with somewhat lighter spots; three small black subapical spots in whitish rings, small double spots at the margin; an angular line, no spot, above the inner margin. Hindwing blackish, fringe lighter. Utah.
- philomela.* **G. philomela** Schs. (184 a). Forewing reddish flesh-coloured grey, with scanty striae forming irregular lines; interior area shaded darker; a small round black punctiform spot at the cell-end. Hindwing dark brown. Brazil (Rio de Janeiro).
- nudaria.* **G. nudaria** Schs. (182 f). Forewing rather dark grey, somewhat diaphanous, clouded; near the base with an interrupted black transverse streak from the costal margin and a shorter one through the cell. Guatemala; Costa Rica; Panama; Venezuela and Guiana.
- tucumanata.* **G. tucumanata** Dgn. (184 a). Forewing dark grey; densely dusted black, the striae reticular; a whitish area at the cell-end encloses a bent black discal streak; only the ♀ type from Argentina is known.
- rolis.* **G. rolis** sp. n. (184 a). Forewing dark grey, irregularly reticulated black, a subterminal line being most conspicuous; a slightly oblique black streak at the cell-end. Hindwing somewhat lighter grey, interruptedly reticulated. Expanse of wings: 29—39 mm. Argentina (Tucuman); type in the U. S. National Museum.
- actileuca.* **G. actileuca** Dyar (184 a) has short and broad wings. Forewing dusted dark grey, lighter at the margin; 3 small black diffuse spots subapically; a whitish bow encircles the cell below and outside as far as the costal margin; no discal spot present. Hindwing light, speckled with dark, and with small dark marginal spots. Mexico: only the type is known.
- nigrisparsata.* **G. nigrisparsata** Dgn. (= *giacomellii* Köhler) (184 a) resembles *rolis*, hindwing of ♂ whitish, the reticular markings coarse and thick, forming a triangular spot above the middle of the inner margin and a subterminal row of spots. Hindwing of ♀ reticulated grey. Argentina. DOGNIN's type is a ♀, before me there are 8 other ♀♀ and 1 ♂ from La Rioja, taken by GIACOMELLI, so that the species founded by KÖHLER, based upon 1 ♂, is most probably the same species.
- francesca.* **G. francesca** Dyar (184 b). Clouded dark grey with quite indistinct traces of dark markings formed by somewhat coarser reticulations. Hindwing blackish. Florida, only the ♂ type is known.
- cinerea.* **G. cinerea** Schs. (184 b) is larger than *francesca* and more finely reticulated; brownish grey with small indistinct dark strigiform spots on both wings; forewing with small dark marginal spots extending also to the fringe. Guatemala and Costa Rica.

G. rabidan *sp. n.* (184 b). Small, hindwing black; forewing dark grey, the basal two thirds shaded *rabidan*. with brownish, the marginal third with coarse black reticular markings, the basal part only slightly marked black. Expanse of wings: 20 mm. Only 1 ♀, no habitat mentioned, type in the U. S. National Museum.

G. cornelia *Neum. & Dyar* (= *caerulea Dalla Torre*) (184 b). The subsequent species exhibit a more *cornelia*. triangular shape of the forewing with but very insignificant markings. Body and wings white, slightly tinged brownish behind the cell, a rather large round punctiform spot at the cell-end; small strigiform spots at the inner margin and on the hindwing. Colorado.

G. theodori *Dyar*. White, the thorax slightly mixed with light grey; basal half of forewing without mark- *theodori*. ings, only a few black dots at the costal and inner margins, with large purple grey spots behind the cell, traversed by the white veins; distal half of hindwing striated light purple grey. — **kunzei** *Dyar* is somewhat smaller, *kunzei*. the postmedian spots are inclined to be confluent. Arizona.

G. durangona *Schs.* (184 b) differs from *theodori* in the large spots in the postmedian area being replaced *durangona*. by but scanty small strigiform spots; a few reddish striae at the inner margin. Colorado.

G. carla *Dyar* is the same, but the grey markings in the distal area are more reticulated. It is doubtful *carla*. whether it is a separate species. South California.

G. lucretia *B. & McD.* is larger; forewing white with a dark macular band from the centre of the inner *lucretia*. margin obliquely to the upper cell-angle. Texas.

G. albicosta *Schs.* (184 e). Mouse-coloured, forewing shaded reddish at the base and apically, the costal *albicosta*. margin rather broadly greyish white, the wing covered with indistinct dark striae. Hindwing grey. The ♂ frenulum is a stout short thorn, finely pointed. Costa Rica.

G. pallidicosta *Schs.* (184 e) is smaller than *albicosta*, hindwing white with small grey marginal spots *pallidicosta*. and fringe. The ♂ frenulum is a delicate fine short thorn. Brazil.

G. nais *Drc.* (= *naida Dyar*, *albipuncta Schs.*) (182 f). Grey with a reddish tint and a slightly darker *nais*. discal cloud on the forewing and a silvery white marginal stripe at the inner margin from the base to the middle; indistinct darker striae and a white discal dot are occasionally traceable. Hindwing of ♂ whitish grey, of ♀ somewhat darker. The ♂ without a frenulum. Mexico, Guatemala, and Costa Rica.

G. anna *Dyar* (184 c) resembles *nais*, but it is darker grey without the reddish brown tint. ♂ likewise *anna*. without the frenulum. Florida.

G. lotta *B. & McD.* (184 e). Like *anna*, but the fringe more spotted; a white discal spot is usually *lotta*. absent, basal area slightly darkened with brown. Hindwing dark smoky brown, slightly reticulated, fringe speckled. Arizona and Colorado.

G. neceros *Dyar* (184 e). Dark reddish brown with a dark oblique shadow through the centre of the *neceros*. wing. Hindwing blackish brown. ♂ like the preceding species without a frenulum. Panama.

G. marga *B. & McD.* (184 e). Dark grey, somewhat dustedly strewn with a narrow white discal streak; *marga*. the ♂ has neither a frenulum nor a costal-marginal reverted fold. One specimen lacks the upper branch of the discal vein on the hindwing. South California.

G. ethela *Neum. & Dyar* (184 d). Light grey, spotted darker; a white discal dot at the cell-end and *ethela*. a black one below it. ♂ without the frenulum and the costal-marginal reverted fold. The larva lives in *Purshia tridentata*. Colorado, Utah, and Nevada.

18. Genus: **Psychogena** *Schs.*

The genus has the same neuration as *Givira*, but the veins 6 and 7 on the hindwing are on a long stalk, and 7 and 8 are connected by a bar. Hindwing of ♂ sharply triangular.

Type: *P. miranda Schs.*

P. miranda *Schs.* (184 d). Body shaggily clad, abdomen with lateral black scale-tufts. Forewing reddish *miranda*. brown, interruptedly reticulated, a black spot basally, a triangular one at the inner margin, and a large round one at the cell-end; the apex is broad, the distal margin narrow black. Hindwing black. Only the ♂ type from Costa Rica is known.

P. duplex *Schs.* (184 d) has monotonously blackish brown forewings. Hindwing whitish, diaphanous, *duplex*. black along the inner margin. Only 1 ♂ type from French Guiana is known.

19. Genus: **Langsdorfia** Hbn.

Discal vein forked in both wings; veins 6 and 7 of hindwing separated and almost parallel or at least almost separated. The ♂ typically lacks the frenulum and the costal-marginal reverted fold, but the costal margin of the hindwing is very often widened, which may accomplish the same purpose of holding together the wings in flying. The typical forms exhibit veins 7 and 8 connected near the cell-end by a bar. Everything else as in *Givira*.

Type: *L. franckii* Hbn.

- franckii*. **L. franckii** Hbn. (182 h). Lilac brown, lighter along the costal margin and spotted here, broadly shaded dark at the margin, with a thick light arcuate streak at the apex, the subterminal area lighter lilac; a dark shadow extends from the base through the cell; 3 or 4 silvery spots near the base towards the inner margin, the spot above vein 1 being the largest. Brazil and Bolivia.
- lunifera*. **L. lunifera** sp. n. (184 d). Like *franckii*, but the dark median shadow is broader and despatches a wedge-shaped branch to the costal margin behind the middle, by which a light crescentiform spot is cut off; the apical light arcuate streak is thinner and less bent. Mexico, San Salvador, Guatemala; Costa Rica; Trinidad; Venezuela; Colombia; French and British Guiana. Type in the U. S. National Museum. The larva, according to MOORE, in the lower end of the stalk and main roots of "pigeon pea".
- rufitincta*. **L. rufitincta** sp. n. (182 h) is likewise very closely allied to the two preceding species, shaded dark, the markings less contrasting, more or less tinged rusty brown subapically and along the inner margin; the light subapical spot is more quadrangular than crescentiform and less sharply defined along the lower edge than in *lunifera* of which species it may be merely a form. Mexico; San Salvador; Guatemala; Venezuela. Type in U. S. National Museum.
- dukinfieldi*. **L. dukinfieldi** Schs. (182 h) is dark mouse-coloured brown with a white-dusted subterminal band which is angular subcostally and bends back from the anal angle to before the middle of the cell; near the base a dark brown bent lobate band enclosing a silvery spot; a mahogany-brown triangle at the cell-end and a larger one in the angle of the white subterminal line. Hindwing of ♂ light, of ♀ dark brown. Brazil and Argentina.
- adornata*. **L. adornata** Dgn. (184 d) differs from *dukinfieldi* in the whitish submarginal line not bending up to the cell; large whitish ringed spots behind it; the angularly lobated basal band contains a silvery spot; a narrow discal spot despatches a stripe outward along vein 5. Only the ♂ type from Ecuador is known.
- plataea*. **L. plataea** Schs. (184 e). Dark brown, the markings not very prominent, the veins striped light; a large oval silvery spot near the base with a small one before it; silvery spots at the margin between the veins. Hindwing without a costal convexity, but a long slender frenulum is present, penetrating into a reverted fold of the costal margin of the forewing. Brazil and Argentina.
- moche*. **L. moche** Dgn. (184 e). Blackish brown with blackish reticular markings and angled striae; an irregular subterminal line of spots. A large oval yellowish silvery spot near the base below the cell; inner margin red-brown. Hindwing light. Only the 1 ♂ type is at hand with a typical *Langsdorfia* structure. Peru.
- malina*. **L. malina** Dgn. (184 e). Dark brown, of a variable tinge; right across the apex there is a dark brown triangular spot with a more apically situated dot, continued as an irregular subterminal line of spots, which is outwardly bordered with silvery whitish; a large subbasal spot with a yellowish silvery spot below; disc cloudily darkened, straightly cut off inside. Colombia; Bolivia; Ecuador and Peru.
- metana*. **L. metana** Dgn. (= *argentata* Köhler) (184 e). Light brown, the markings distinctly prominent; as in *malina*, a large, below narrowed spot subterminally at the costal margin, continued below as a narrow line feebly bordered with light; a triangular spot in the disc and a quadrangular subbasal spot with an oval silvery spot below it on vein 1. Hindwing dark. The species is closely allied with *dukinfieldi*. Argentina.
- coresa*. **L. coresa** Schs. (184 e). Dark brown with many small darker spots; a large costo-subapical spot bordered with light, continued below in subterminal punctiform spots. Body very strong, the structure of the body typical. Colombia.
- watsoni*. **L. watsoni** Schs. (= *invetita* Dgn., *obscura* Köhler) (184 f). Forewing brownish grey, of a variable tint and distinctness of the markings, the latter being brownish black; the apical spot is more or less distinctly continued below as a dark, lighter bordered submarginal band; the wing slightly marked with lighter small diffuse spots and a few striae; a small triangular spot in the middle of the inner margin and a larger one near the

base, containing a silvery spot; dark submarginal spots at the ends of the veins. Hindwing dark. Brazil; Paraguay and Argentina.

L. minima Dgn. (184 f). Forewing grey mixed with brown; the subbasal spot shows angular projections *minima*, and instead of the silvery spot a spot of the ground-colour; small costal-marginal spots, a submarginal line and interrupted reticular markings are dark brown; discal shadow reddish brown. Hindwing dark. A very small species; the ♂ shows in spite of a costal-marginal projection on the hindwing also a slender frenulum and a corresponding costal-marginal reverted fold. Ecuador.

L. garasia Dgn. (184 f). Brown, the spots dark brown; a large lobate, submedianly thickened spot is *garasia*, at the base, bordered with silver outside, and 3 large roundish-angular spots bordered with silver are in the distal area; rather large spots at the costal and distal margin, the latter ones extending to the fringe. Structure of frenulum as in *minima*. Veins 6 and 7 of hindwing either separated, arising together or even stalked. From Argentina.

L. argyrotoxa sp. n. (184 f). Dull wood-brown, with a large lobate dark brown subbasal spot bordered with silver outside, submedianly forming a larger inward lobe; a median band thickened at the inner and costal margins, narrowed or interrupted in the middle; a fine subterminal line is thickened at the anal angle, without a silver border; a blackish shadow behind the cell between the veins; hindwing blackish. Structure of frenulum as in *minima*. Expanse of wings: 25 mm. Peru (Lima); the type in the U. S. National Museum.

L. bellaria Dgn. (184 f) is hyaline without scales in the distal area of the forewing and on the whole hindwing, but the fringes of both wings are intact; the ground is almost white with 5 large dark brown spots and many small spots and striae. Structure of wings typically *Langsdorfia*-like, without a frenulum. Only the ♂ type known from Colombia.

L. brunneomaculata sp. n. (184 f). Forewing light wood-brown with large round red-brown spots bordered with white; a large bent subbasal spot, a round one at the cell-end extending to the costal margin; a submarginal row of 3 spots, the lowest small and produced to the anal angle. Hindwing whitish with a double dark marginal line. Of a typical *Langsdorfia* structure, without a frenulum. Expanse of wings: 36—45 mm. The species is very much like *L. marmorata* Maassen which I do not know in nature, but it shows single differences. Peru (Lima); type in the U. S. National Museum.

L. ambigua Hbn. (= *tigrina* Bsd.) (184 g). Light tan-coloured, marbled with light brown spots bordered with whitish; hindwing whitish with light brown marginal spots and apically with a submarginal row. Of a typical *Langsdorfia* structure. Argentina and Uruguay.

L. chielin Dgn. (184 g) resembles *ambigua*, but the dark brown spots are narrow and prolonged with white edges; these spots form a series near the margin, a larger one is below the cell, narrowed at the end and bent downward. Structure typical. Peru.

L. demissa Maassen I do not know in nature, but the figure is so much like a dark *aquila*, that I believe to be right in ranging it here; separated by blackish hindwings. Ecuador.

L. aquila Dgn. (182 i). Forewing reddish brown, brighter at the costal and inner margins, the veins rather broadly white. Hindwing light whitish or tinged with brown. Of the typical *Langsdorfia* structure, but owing to the broad obtuse wings and the strongly bipectinated antennae it looks like a *Lasiocampida*. Colombia and Bolivia.

L. basiplaga Schs. (184 g). Forewing long triangular, grey, coarsely striated, with a large triangular brown basal spot and discal spot. Hindwing with a long slender frenulum which penetrates into a projection of the base of vein 12 of the forewing. Forewing with a tiny areole arising from vein 10, the veins 7 + 9 stalked from the end of the discal cell; described as *Ravigia* to which it cannot belong, because the discal veins of both wings are stalked. British Guiana.

L. macrochir Schs. (184 g). Forewing light tan-coloured covered with roundish brown spots, partly darker, partly lighter; a larger one is subterminal on vein 4, and one subapical. Hindwing similar, but less distinctly spotted. Structure normal. Brazil (Rio de Janeiro).

L. caestroides H.-Schäff. (184 g). Ground-colour light yellowish straw-coloured, dark at the margin; a large oblique dark brown subbasal spot extends from the costal margin to vein 1; behind the cell above the discal veins as far as near the anal angle there is a large dark area composed of red-brown, blackish brown and violettish grey small quadrangular spots. Only 1 ♀ before me. Brazil (Rio de Janeiro).

L. centrosoma Dyar (182 i). Dark grey, reticulated black; a narrow black line in the antemedian area and accumulated black and violettish grey scales behind the cell-end. ♂ antennae biserrate and tuftedly ciliated. Hindwing with a moderately slender frenulum penetrating into a convexity at the base of vein 12 of the forewing; veins 6 and 7 of hindwing well separated, no bar connecting 7 and 8. Mexico.

- beatrix*. **L. beatrix** Schs. (184 g). Forewing light grey, interruptedly reticulated black, with a black antemedian oblique band, another one across the apex. Costal margin of hindwing with a moderate lobe, the frenulum is a small degenerated small thorn without a function; a bar at the cell-end connects the veins 7 and 8. Guatemala.
- infans*. **L. infans** sp. n. (184 h) is darker grey than *beatrix*, with striated reticulations, the interior black line less oblique, another line in an opposite oblique direction extends from the centre of the inner margin to the cell, a third irregularly across the apex and an arcuate streak across the anal angle which is situate in dark clouding; reticular markings at the margin show fork-like formations with the ends of the dark markings. Hindwing light grey, with a short stout frenulum which is evidently without function; a bar between 7 and 8; antennae bipectinate. Paraguay (San Bernardino); type in the U. S. National Museum.
- sobrana*. **L. sobrana** Schs. (184 h). Forewing dark reddish brown, scantily striated grey, a lighter stripe along the median vein extends to the anal angle widened above 2 and 3. Hindwing red-brown, without spots. Of the normal *Langsdorfia* structure without the frenulum. French Guiana, Bolivia, Brazil (Sa. Catharina, Novo Friburgo, Amazons).
- palmata*. **L. palmata** B. & McD. (184 h). Forewing white, strewn with dark smoky brown along the inner margin, below the cell as far as the anal angle and behind the cell along the veins 5 and 6, the latter up to the apex, also the veins, triangularly widened towards the margin, striped brown. Hindwing light smoky brown with darker veins and whitish fringe. Arizona.

20. Genus: **Puseyia** gen. nov.

Neuration the same as in *Givira*, but the discal veins on both wings plain, not forked; veins 6 and 7 of hindwing on a long stalk, a bar between 7 and 8 at the cell-end. The ♂ frenulum is a moderately thick thorn penetrating into a fold of the subcosta of the forewing. Antennae shortly bipectinate.

Type: *P. puseyiae* Dyar.

- puseyiae*. **P. puseyiae** sp. n. (184 h). A larger light brown species, with traces of reticular markings, an oblique dark line through the centre of the wing with a more oblique side-line inside below; a bent dark line encircles the anal angle, filled with violettish grey inside. The median area between these lines is lighter inward, darker outward. Hindwing dark greyish brown. In the marking it resembles *Inguromorpha roseobrunnea* Dogn. Expanse of wings: 40 mm. Peru (Callao); type in the U. S. National Museum.
- hiscelis*. **P. hiscelis** sp. n. (184 h) is a smaller species, light grey, with darker striations and reticulations; a black spot in the middle of the inner margin above vein 1, absent in the ♀. Hindwing without a bar between 7 and 8. Expanse of wings: ♂ 20—23 mm; ♀ 24 mm. Amazons (Coary; Fonteboa); type in the U. S. National Museum.
- ban*. **P. ban** Dyar (184 i) is darker grey, speckled dark; a black spot above the middle of the inner margin, 3 behind it in one line towards the apex, and a subbasal spot before it, all these, particularly the large median one is bordered with lighter yellowish; an indistinctly marked spot at the cell-end. Hindwing dark grey, the veins 6 and 7 on a very long stalk, no bar between 7 and 8. Expanse of wings: 22 mm. The only type known is without the abdomen. From La Rioja, Argentina.

21. Genus: **Inguromorpha** H. Edw.

Discal veins on both wings plain, not forked. Veins 6 and 7 of hindwing separated, a bar connects 7 and 8 at the cell-end; ♂ with a slender frenulum penetrating into a costal fold of the forewing. Antennae bipectinate.

Type: *I. slossonii* H. Edw.

- basalis*. **I. basalis** Wkr. (= *slossonii* H. Edw.) (169 h). Whitish grey, reticulated black, with a straight narrow black band near the base and an arcuate streak or a rounded spot before the apex. Hindwing dark grey. WALKER described the species from an unknown habitat, but I ascertained later the identity with EDWARD's *slossonii*. Florida; Missouri; Texas; Mexico (Santa Cruz).
- sandelphon*. **I. sandelphon** Dyar (= *clymene* Schs.) (182 i). Violettish grey, dusted darker in the interior half; irregular bands of quadrangular spots are in the basal and median areas, a thick bent band across the apex. Hindwing blackish. Veins 6 and 7 of hindwing on a short stalk. Mexico and Guatemala.
- arcifera*. **I. arcifera** Dyar (= *gabriel* Dyar) (182 i). The light lilac ground which only remains as the borders of the spots is densely dusted with brown; the interior band is divided into spots, the exterior one oblique, extinct above, bordered with light outside; a thick shadow from the anal angle up to above vein 5 contains a black arcuate line; a brown bow at the apex is bordered with white. Hindwing dark with lighter reticulated striae. South Texas; Mexico.

I. triarectata *Schs.* is similar to *acrifera*, but the light lilac ground predominates; the band in the basal area coherent, dusted, the anal arcuate streak also coherent, confluent with reticular markings. Only the ♂ type is known. French Guiana.

I. roseobrunnea *Dgn.* (169 h). Forewing rosy grey, the basal area almost as far as the middle reddish brown, bordered by a black oblique line which extends from the interior third of the inner margin to the middle of the costal margin; forewing with scanty spotted reticulations; a thick black streak across the anal angle encloses a blackish area and bends up to the costal margin by 3 or 4 small punctiform spots. Hindwing blackish, striated darker. Only the ♀ type (without its abdomen) is known. French Guiana. *roseobrunnea*.

I. polybioides *Schs.* Ground-colour of wings whitish, brown costal-marginal and inner-marginal shadows are connected in the middle by a band; reticular markings form a tridentate bow above the anal angle, a thick irregular spot is at the apex. Only 1 ♂ type from Brazil is known. *polybioides*.

I. itzalana *Stkr.* (169 h) resembles no other species; large, forewing grey, strewn with black atoms; the veins striped black with single interruptions; black striae at the base of the inner margin and before the apex. Hindwing lighter grey, similarly strewn. Arizona. *itzalana*.

I. polybia *Schs.* (= *inguromorpha Schs.*, *crassiplaga Schs.*) (182 i) resembles *basalis*, the light ground is intermixed with whitish spots, reticulated black, with a fine interior oblique line and a bow above the anal angle, a bent black spot at the apex, slender or also thicker. Hindwing without a bar connecting 7 and 8. Guatemala; Panama; Colombia; Venezuela; Guiana; Brazil. *polybia*.

I. ramulosa *Dgn.* has blackish grey wings marked as in *polybia*, but without white spots and with finer reticular markings; the apical spot is not more prominent than the other reticular markings. Argentina. *ramulosa*.

I. entone *sp. n.* (169 h). Thorax and forewing yellowish grey; abdomen light at the base, with a black band behind it, laterally shaded dark. Forewing with a black interior band which is widened at the costal and inner margins and united with a bent band above the inner margin extending to the cell-end; distal half with spotted reticulations, in the only type with hardly any scales caused by flying, though one wing exhibits yet a round black spot before the apex. Hindwing grey, densely reticulated black. Expanse of wings: 39 mm. Panama, La Chorrera; type in the U. S. National Museum. *entone*.

Family: Hepialidae.

By R. PFITZNER †. Revised by M. GAEDE.

A strange group differing from all the other lepidopteral forms and separated by extremely old marks of distinction; the “*Jugatae*”, thus styled by COMSTOCK because of their being provided only with a skinny lobe (jugum) instead of the frenulum (*frenatae*), comprise the two families of the *Micropterygidae* inclusive of the *Eriocraniidae* and *Hepialidae* (*Micropterygina*). The *Hepialidae* have developed from the *Micropterygidae* without any closer relations, as there are no connecting links. The *Micropterygina* are the most primitive lepidopteral order and, in their neurulation, they immediately approximate the *Trichoptera*. The age specially of the *Hepialidae* is traced back to the Jurassic epoch, when this family may have been represented by gigantic forms, lepidopteral “saurians”, only single remnants of which have been left to this day, as for instance the gigantic *Phassus giganteus* (100 d) in South America. The marks of the primitive habitus of the *Hepialidae* are both morphological and biological. The extremely slim shape similar to that of a dragon-fly, most obviously exhibited by the *Phassus* which are especially well developed in America, the mostly very feeble antennae and the absent palpi and oral parts, the strong shaggy legs, the peculiar position of the forewings and hindwings exhibiting an interstice, the hair on the wing-membrane, the more or less hair-like scales on the wings, the neurulation being the same (12 veins) on all the four wings, the subterranean or endoxyle habits of the larvae which resemble the grubs of cockchafer (bare with tubercles and a hard shiny head and strong biting organs), the mobile pupa provided with limbs, the peculiar flying habits of many species resembling those of certain Ephemeroidea — all these peculiarities prove the *Hepialidae* to be one of the primitive types of lepidoptera. This is corroborated by the fact that most of the members of this family are to be found in the isolated Australian Region abounding in archaic forms. America is not only absolutely but also relatively poorer, since only about 90 species occur there, compared with more than 100 Indo-Australian species. We must, moreover, consider the immense extent of the region and, besides, the enormous development of its lepidoptera, in order to be able to realize the difference of the two faunas compared; especially since, including the forms and synonyms, more than 15 000 names of American *Rhopalocera* have been dealt with in Vol. V (GAEDE).

Owing to the immense extent of the region covering two continents, the *Hepialidae* show of course a very different exterior in the various parts of this range. The North-American (neoarctic) forms are closely related to the European and palaearctic ones in a restricted sense, belonging for instance to our *ganna*, *hectus*, *velleda* and *carna* groups. The habitus of the antarctic forms (*Pielus*, *Callipielus*) approaches that of the South-Australian and Tasmanian species. Between the two subregions, in the tropical zone extending from Mexico to Paraguay, the *Phassus* and *Dalaca* are inserted, to which most of the American *Hepialidae* belong. Great numbers of other forms are yet to be expected from this region, since every expedition of collectors will probably yield new forms.

The *Hepialidae* are very unequally distributed over America. In general, the mountainous districts of the west (Rocky Mts., Cordilleras) are much preferred. In North America, California abounds most in Hepialid species. From the Equator to the southern point of America, the number of species decreases remarkably; quite poor, however, is the subregion of the Antilles from where, as far as I know, not any Hepialid species has yet been brought. A peculiar fact, which, however, is not unique (cf. Madagascar); still, no satisfactory explanation for it is known to me *).

With the American *Hepialidae* we are still more confronted by the difficulty of a somewhat unbroken description than with the Indo-Australian ones. Especially the South-American forms, above all *Dalaca*, need sifting, since a lot of undescribed material, which is constantly increasing, sticks in the collections. Another difficulty is offered by the impossibility of obtaining authentic specimens. Nearly every family presumably contains descriptions that are based upon a single type. Yet this is most extensively the case with the *Hepialidae*, especially the American ones, more perhaps than with any other lepidopteral group.

*) The cause may be that the *Hepialidae* are an old family and therefore to be found more in (the old) Australia, but hardly in the (volcanic) New Antilles (GAEDE).

The Hepialid genera occurring in the American Region are: *Hepialus* F. with the subordinate genera *Phymatopus* Wlgr., *Sthenopsis* Pack. and *Cibyra* Wkr., then *Philaenia* Ky. (= *Pharmacis* Möschler), *Dalaca* Wkr., *Triodia* Hbn., *Pielus* Wkr., *Callipielus* Btlr., *Philanglaus* Btlr., *Osrhoes* Drc., *Phassus* Wkr., *Pseudophassus* Weym.

1. Genus: **Hepialus** F.

Head and thorax with woolly hair. Antennae shorter than the thorax, eyes bare, no accessory eyes. Palpi tiny; proboscis absent, two round knots instead of it. All the wings with 12 veins and an inserted cell between veins 4 and 5. Hindwing also with 2 or 3 branches arising from the anterior median vein and extending into the costal margin. Larvae subterranean, on roots. Metamorphosis in a web. In America more in the west, in mountainous districts. Besides the genuine *Hepialus* the subgenera *Phymatopus*, *Sthenopsis* and *Cibyra* are represented.

a) *Hepialus* F.

- hectooides*. **H. hectoides** Bsd. (= *inutilis* Edw., *modestus* Edw., *sangaris* Strck.) (99 a). With this species which is similar to the European *hectus*-♀ and has also the same shape and size we begin the series of the North-American *Hepialus*. Forewing brownish ochreous with dark red markings. Hindwing brownish grey, margin ochreous.
- lenzi*. California, Arizona. I received specimens from Obispo, where the species flies in May and June. — **lenzi** Behr (99 a) is mostly smaller, more reddish, with a very indistinct marking.
- sequoiolus*. **H. sequoiolus** Behr (= *mendocinulus* Behr) (99 a) is a closely allied species, likewise from California. Darker, with more greyish brown markings. It inhabits the higher parts of the Rocky Mts.; I received specimens from Colfax, Cal., 5000 ft. FRANCIS WILLIAMS reports details about the larva and its habits. Head slightly bilobate, round, partly hidden below segment 1, diaphanous reddish brown, oral parts black, size 4 mm, with a few hairs. Body cylindrical, segments 2 and 3 somewhat thickened, 12 and 13 tapering. The larger segments with a subdivision, wood-brown, segments 12 and 13 dingy white. Body: dorsal shields with tubercles set with brownish hairs, thoracic legs yellow; all the thoracic segments with large umber-brown dorsal shields of different sizes. On the sides of all the segments (except 13) there are 4 tubercles each above the spiracles in two rows. Segments 4, 5, 10, 12 with one large dorsal tubercle each with 2 hairs. — In trunks of *Eriophyllum staedifolium* and roots of *Helenium puberulum* and in the large yellow lupine. It bores a longitudinal tunnel close above the soil and closes the opening with its excrements. Larval stage about 2 years, grown up in June. In captivity the larvae attack one another. Common near San Francisco, Alameda,
- behrensi*. Mendocino. — **behrensi** Stretch (= *tacomae* Edw.) is a very closely allied species, likewise from California. Salmon-coloured brown, with hardly any spots, 3 parallel bands, the 1st and 2nd in the lower third spotted
- montanus*. with silver, the 3rd often absent. — **montanus** Strck. may also belong to this group. Dark brown or yellowish brown, 3 paler bands of spots, bordered with dark, hindwing of the same colour or darker. Size same as of *behrensi*: about 55 mm. The synonyms *anceps* Edw., *baroni* Behr, *desolatus* Strck., *rectus* Edw. are perhaps identical with subordinate forms of the apparently very variable species. Widely distributed, California to Nevada.
- californica*. **H. californica** Bsd. (99 a), very closely allied to the European *carna* forms the transition to the following group. Forewing dark grey, in a certain exposure to light we see towards the apex a few whitish parallel stripes enclosing smaller round spots of a darker colour. Hindwing blackish grey. Size of *hectus*. It inhabits more the higher mountains of California, Plumas (10 000 ft.), Pomona. June.
- mustelina*. **H. mustelina** Pack. (99 a) and the following species represent the European *velleda*-group in North America. *mustelina* is brown, forewing finely speckled with a lighter brown and an irregular whitish band
- labradoriensis*. along the distal margin from the interior angle to the apex. — **labradoriensis** Pack. (27 mm) is a form with a black shadow above this band along the inner margin. The specimens from the United States seem to be somewhat larger and paler, semitransparent, judging from 1 specimen of my collection from Massachusetts
- gracilis*. (33 mm); North-Eastern America. — The allied **H. gracilis** (= *furcatus* Grt.) is likewise feebly scaled, dark brown, the whitish transverse band is rather broad, but not dentate, the rest of the wing clouded dark with black and brown scales without distinct spots; distal margin white, fringe spotted black. 33 to 40 mm. Northern States as far as Canada.
- lemberti*. **H. lemberti** Dyar (99 a). Dull ochreous, with rows of hyaline dark-edged spots of a most variable distinctness and size; some may be absent, others confluent. Hindwing blackish. 30—35 mm. California, on high mountains (1 specimen from Cisco, taken in June).

We append now first of all the species from the antarctic zone of South America.

- staudingeri*. **H. staudingeri** Wgn. (*antarcticus* Stgr.). 1 specimen from Paramo (Sebastian Bay on the eastern coast of Fuegia); the name had to be changed, because *antarcticus* was already preoccupied by a South-African species published by WALLENGREEN. Description according to STAUDINGER (Magelh. Sammelreise): 1 ♀, 59 mm. Fringe longer than in *Pielus luteicornis* (pl. 99 h), a band-like marking on the forewing, similar to

that in the palaearctic species *amasinus*-♀*) or *varius*. Ground-colour light smoke-brown or greyish brown, but not so transparent as in *luteicornis*. The broad light fringe speckled dark. 7 or 8 tiny oval round spots before the lighter places in the margin. Behind them a long narrow silvery white transverse band beginning 2 mm below the apex and terminating at the 1st median branch, almost parallel with the distal margin. Distally bordered by a slightly undulating dark transverse line, inwardly by a twice as broad dark band. The latter is followed by a light greyish brown transverse line which is partly bordered with dark inwardly and behind which, especially upward and downward, there is an irregular whitish line bordered with dark. At the 2nd median branch, this white line unites semicircularly with a short whitish linear marking extending to the lower part of the discal cell. 2 or 3 tiny oval dark spots below the costal margin, about 6—8 mm distant from the apex; somewhat farther inward, below between veins 7 and 8, there is a short white longitudinal streak pierced by dark; below the basal half of the costal margin in the upper part of the discal cell which is long here, there is a long whitish longitudinal streak bordered with dark above; a similar one seems to have been before the inner margin above the submedian vein. This part of the wing is unfortunately rubbed off, but it has contained larger dark patches, on the left forewing one notices yet that the basal part between the median vein and the median branch was filled with dark. On the dark smoke-brown under surface of the forewing only the white distal-marginal band shows feebly through; fringe less speckled dark, only the extreme tips remain light. Hindwing dingy greyish brown, somewhat lighter on the inner-marginal part, irregular lighter places are hardly discernible; fringe very feebly speckled dark in the middle. Hair of thorax dark olive brown, vertex lighter grey. The short slightly serrated antennae dark brown, the thin dark palpi, 1½ mm long, hang downward. Legs hairy, olive brownish grey; tarsi and abdomen more violettish grey.

H. dimidiatus Berg. Description according to BERG. This species of which only 1 ♂ is at hand, collected in Concepcion (Chile) on the 26th of February 1879, is easily recognizable by the yellow middle part of the forewing somewhat forming a longitudinal band; the costal third and the middle basal part of the inner margin is of a dark brownish grey strewn with a few dark dots. Head, palpi, anterior part of thorax, and the costal third of the inner margin, the marginal dots of the forewing as well as the legs brownish grey. Length of forewing: 42, of hindwing: 35 mm. Chile. *dimidiatus*.

The following species are from the neotropical part of America:

H. helga Schs. Body and forewing pinkish reddish yellow, with very fine dark rings and lines in the marginal third and at the inner margin. Hindwing salmon-coloured, more pink at the margin. Broad olive grey lines at the veins near the margin are connected by similar shadows. 56 mm. According to 1 ♀ from Sa. Catharina. *helga*.

H. munona Schs. Thorax cinnamon red, abdomen paler. Forewing ochreous orange, paler at the margin. Costal margin narrowly dark brown, with brownish spots, not extending to the cell, a few spots also at the inner margin. Slightly darker from the base of the cell to the middle of the inner margin, pinkish brown below it. Hindwing pale orange. 35 mm. 1 ♂ from Sa. Catharina. *munona*.

H. paropus Drc. Forewing yellowish fawn-coloured. Costal margin slightly shaded with yellow, head, thorax, abdomen and legs yellowish fawn-coloured. Antennae dark brown. About 44 mm. Ecuador (Sarayacu). *paropus*.

H. pharus Drc. (185 a). From Guatemala, Las Mercedes (3000 ft.) and Duenas (CHAMPION); Costa Rica, Irazzu 6—7000 ft.); the figure according to a specimen from Las Mercedes, somewhat darker than the others; the specimen from Costa Rica is much paler; that from Duenas is intermediary. Forewing dark brown, spotted lighter. A large brown spot below the cell-end. Behind it an exterior and submarginal dark brown band. One short silvery streak each in the base of the cell, at its end near the apex. Hindwing darker, with reddish brown hair at the base and inner margin. 56 mm. *pharus*.

H. pretiosus H.-Schäff. (185 a). Thorax olive brown, abdomen lighter, forewing rather variegated. Yellowish brown at the base at the costal margin and inner margin. Of the same colour is the V-shaped band from $\frac{2}{5}$ costal margin to $\frac{2}{3}$ inner margin and from there again to $\frac{2}{3}$ costal margin. Beginning from the base of the costal margin, the band is set with small red spots. Greenish before it in the cell and behind it at the distal margin. Dark brown at the middle of the inner margin and spot-like between the sides of the V-shaped band. Hindwing pale yellow, rusty yellow at the margin. ♂ 52 mm. Brazil. *pretiosus*.

b) P h y m a t o p u s Wllgr.

A circumpolar group represented in the palaearctic region by *ganna* and *macilentus* with subordinate forms. Forewing brown with white bands, of an Arctiid-like habitus.

Ph. hyperboreus Mschlr. (= *pulcher* Grt.). Shape and size of *ganna* which it resembles so much that some American authors formerly considered all the *hyperboreus* to be forms of *ganna*. Forewing pale brownish with a salmon-coloured tinge on the forewing; easily discernible from the form *mcglashani* (99 a) by the light angular band being interrupted several times and the other light marking being also broken up into smaller

*) Cf. the remark to this species in Suppl. II, p. 247 (Dr. SEITZ).

spots, as also in many *ganna*-♀. According to BARNES & BENJAMIN, *hyperboreus* shows silvery spots on the forewing, the hindwing with a dark brown band from the apex almost to the base of the wing. — American authors have mistaken the species or form **roseicaput** Neum. & Dyar for *hyperboreus*. *roseicaput* is sexually dimorphous. Forewing of ♂ with an open V-shaped silvery marking, not very irregular, only partly split up, the other silver marking divided. Hindwing blackish brown, pink at the margin. The ♀ has a more or less black V on the forewing. British Columbia, Oregon. — **mutatus** Barn. & Benj. denotes ♀♀ which are exceptionally marked like the ♂. From Oregon. — **demutatus** Barn. & Benj. are ♀♀ with a more or less unmarked forewing. Oregon. — **mcglashani** H. Edw. (99 a) has a much more irregular V on the forewing, often with one or more spurs on the V, the ♀ also sometimes with a divided V. From California. — **confusus** H. Edw., from Alaska, exhibits (on the left forewing) an oblique silvery E with additional spurs. The marking is divided, the parts connected by black. Hindwing uniformly dark brown. — **pulcher** Grt. has an almost coherent E-marking. Hindwing salmon-coloured dusted with blackish. Colorado, Utah. — The following forms show the silvery marking confined to a broad open V connected with the base. Only at the costal margin 1 or 2 spots, a few below vein 1 and at the base of the fringe. — **mathewi** H.-Edw. (99 a) has a black spot at the cell-end of the forewing. The apical end of the V is mostly black. Hindwing with yellow or salmon-coloured hair at the base. Vancouver I. — **noviganus** Barn. & Benj. may also be a race of *roseicaput*. Separated from *mcglashani* by a more neatly marked V, the marginal spots are always faded also in otherwise distinctly marked specimens. Separated from *mathewi* by the absence of the black spot in the cell-end and at the V outside. Hindwing less spotted. Typical *noviganus* have a somewhat brown or reddish brown ground-colour. From Ontario. — **mackiei** Barm. & Benj. is pinkish salmon-coloured. Alberta.

H. labradoriensis Mschlr. Dark brown sand-coloured. Forewing with a black angular spot in the middle, surrounded by light brown, a straight light band before the margin. Size of *mathewi* (99 a). Labrador.

c) *Sthenopis* Pack.

This well defined and characterized group inhabits the North-Eastern United States as far as Canada. Large species, the size, shape of wings and marking resemble those of *Phassus shamyl* (Vol. II, pl. 54 a). Forewing with silvery or golden maculae.

H. argenteomaculatus Harr. (= *alni* Kell., *argentata* Pack.) (99 b). Forewing with a produced apex, dark brown, marbled grey, two silvery spots near the base. Hindwing brown, apex more or less spotted. 65—105 mm. North Atlantic States. — **perdita** Dyar. Dark brown, marbled sandy brown, the maculae sometimes extinct. Hindwing somewhat diaphanous. Habitat not stated. — **purpurascens** Pack. is more purple brown; from White Mountain larvae: according to BEUTENMÜLLER the head is light yellowish brown above with black oral parts, the body with rows of black hairy dots. The 2nd and 3rd segments paler than the head, legs yellowish. 30 mm. It lives for two years in the roots of alder-trees, in the 3rd it ascends to the trunk. In the spring of the 3rd year it bores itself to the surface, closing the opening partly with refuse and discharging the imago in June.

H. auratus Grt. Yellowish brown with a metallic bronze reflection and indistinctly white-edged spots which are most prominent on the two parallel transverse bands; a posterior transverse line and the submarginal line, the latter with 2 or 3 small silvery white triangles below the apex. 48 mm. New Jersey, New York, New Hampshire. Rare.

H. quadriguttatus Grt. (99 b). From a pale salmon-colour to olive brown, with golden brown bands shaped as in *argenteomaculata*, two costal bands and a marginal one; the latter extended at the interior angle and enclosing a paler shadow; 2 silvery spots near the base of the forewing; hindwing salmon-coloured, more or less reddish. 55—90 mm. In the mountains of New England and farther to the north; Sullivan Mts., 2500 ft., in June; Montreal in June; Winnipeg, Manitoba in July. Assiniboine, Alberta, common. — **semiauratus** Neum. with an intense golden gloss, of the same range.

H. thule Strk. (99 b). Bone-white, brownish ochreous at the costal margin, 2 small silvery spots each close together at the base and in the centre of the wing. 60—75 mm. Canada (Montreal), Wisconsin. July.

d) *Cibyra* Wkr.

The European representative of this subgenus is *H. sylvinus* (Vol. II, pl. 54 g). 5 Brazilian species.

H. dorita Schs. Head and thorax dark brown, abdomen fawn-coloured, forewing violettish brown costally as well as at the inner margin, the space between veins 2 and 7 dull golden, traversed by reddish veins, and dull lilac brown spots edged with reddish. A silvery spot at the base of the cell, another one before vein 2, a large silvery spot at the cell-end, and a series of silvery spots between veins 5 and 7. Hindwing leather-brown, shaded reddish from the base to the distal margin, fringe basally dark, paler at the end. 33 mm. Castro (Parana).

H. poltrona Schs. Head and thorax brownish ochreous, abdomen tan-coloured, forewing brownish *polltrona*. ochreous at the costal and inner margins, ochreous between them, indistinct transverse lines in the distal half, darker than the ground-colour, bordered paler inward. The lines form spots. Hindwing red-brown, somewhat rosy in the cell. 40 mm. Castro (Paraná).

H. dormita Schs. Head and thorax dark brown, abdomen light brown; forewing reddish brown, shaded *dormita*. grey at the basal half of the inner margin and within the exterior line, especially towards the costa; a dark oblique shadow from the subcostal base to the middle of the inner margin. Exterior line fine dark grey, shaded lighter grey and followed by a broad red-brown shadow. Greyish antemarginal spots between the veins. A few silvery spots surrounded by black: one at the base of the cell, a larger oblique one at the cell-end, a few tiny spots at veins 5 and 6 beyond the exterior line, and at vein 2. Hindwing blackish brown, distal margin and fringe light brown, ♀ with white apical spots between veins 7 and 8 as well as 8 and 9. ♂ 40, ♀ 68 mm. Petropolis.

H. brunnea Schs. Body brown, forewing light brown, costa spotted black, a basal row and a double *brunnea*. interior oblique row of dark brown spots, a median row of larger brown spots, prolonged below the costa, and with a fawn tint above the interior margin on both sides. Three silvery spots at the origin of vein 6; a broad exterior brown shadow forms spots below vein 5. These spots are bordered with blackish brown and fawn-colour on both sides. An antemarginal row of dark lunar spots bordered with fawn-colour outside. Fringe fawn-coloured, speckled darker. Hindwing deep blackish brown. 31 mm. Aroa (Venezuela).

H. tupi sp. n. (99 c). 36 mm. The strongly rubbed off specimen at hand exhibits a bright brownish *tupi*. yellow ground-colour. Dark spots at the costa. A Hepialid triangle and an inner-marginal spot pale flesh-coloured. Thorax greyish brown, hindwing and abdomen dark yellowish brown, 1 specimen in Coll. SEITZ. From Southern Brazil (Ypanema).

2. Genus: **Philaenia** Ky. (Pharmacis *Mschlr.*)

Hardly separated from *Hepialus* in the neurulation, according to BUTLER near *Oncopera*. Antennae of the ♂ very short, with two rows of pectinations. Palpi very small, hidden. Anterior and middle legs thick, with long and dense hair as far as the tips of the tarsi, middle legs $\frac{1}{3}$ longer than the former ones. Hindlegs feeble, only $\frac{1}{3}$ of the length of the middle legs. Their femora and tibiae less hairy, the tarsi only with appressed scanty hair. Abdomen projecting beyond the anal angle by $\frac{2}{3}$. Forewing with a rounded apex and a rather straight margin, hindwing somewhat longer than the forewing (MÖSCHLER).

Ph. lagopus *Mschlr.* (99 c). Antennae, head and thorax yellowish brown, abdomen greyish brown, legs *lagopus*. yellow, with brown hair. Forewing yellowish brown, broadly dark brown at the costal margin, a similarly coloured dark stripe from the base along the inner margin and a similar oblique stripe behind the middle of the inner margin towards the margin. The whole wing is crossed by transverse rows of blackish tiny cross-streaks edged with yellowish. Fringe dark brown. Hindwing dark brown, fringe scarcely lighter. Forewing beneath yellowish brown, darker at the margins, spots indistinct; hindwing beneath dark brown, dusted yellowish brown at the margin. 28—35 mm. 2 ♂♂ from Central Surinam. — A form from the Upper Rio Negro and Amazons (Pebas) with a silvery stigma in the cell, the forewing ochreous, hindwing grey, basal parts and apex ochreous, fringe throughout ochreous, may be introduced as a subspecies **omagua** *form. nov.* 36—40 mm. *omagua*.

3. Genus: **Dalaca** Wkr.

Body rather slender, slightly hairy, mouth and palpi stunted, antennae thick, bristle-shaped, abdomen projecting a little beyond the hindwing. Legs rather slender, slightly hairy. Wings rather narrow, costa straight, apex somewhat rounded, distal margin rather oblique and slightly convex. Neurulation similar to that of *Hepialus*. Antennae of ♂ dentate, as long as the thorax, somewhat shorter in the ♀; hind tibiae long-haired. Forms from more than middling sizes to small sizes. Apparently the largest genus inhabiting the whole neotropical region from Mexico to Chile. — Another focus of the genus *Dalaca* is situated in Tropical Africa. Cf. Vol. XIV, p. 555 seq. and pl. 80. — A number of American species were newly established. The names are chiefly derived from the language of the Indian tribes inhabiting those districts.

D. epigramma H.-Schäff. (185 a). Ground fawn-coloured. Abdomen brownish, forewing darker basad, *epigramma*. lighter towards the apex. A white angular line from the base of the wing to the centre of the inner margin and then to $\frac{4}{5}$ of the costal margin. Behind it a parallel white submarginal line. Hindwing pink. 46 mm. Brazil.

D. exclamans H.-Schäff. (185 a) resembles *epigramma*. Discernible by the note of exclamation at the *exclamans*. cross-vein. The white lines are absent. 50 mm. Brazil.

D. assa Drc. (99 c). Forewing from yellowish brown to brown-red, 3 undulate transverse lines from *assa*. the costal margin to the inner margin. A dark central spot sometimes shows a silvery centre. Hindwing reddish. 45—50 mm. Widely distributed and common in Central America, from Guatemala to Panama.

- chiriquensis*. **D. chiriquensis** *sp. n.* (99 b). The ♂ is much larger (75—85 mm), body as long as 39 mm. Darker; forewing more brown; the ♀ with chocolate forewings, hindwings dull dark claret. From the Chiriqui Volcano.
- indicata*. **D. indicata** *Strd.* likewise belongs to this group. Separated from *assa* (99 c) by the following: forewing with rather hard-marked black lighter-edged small roundish and oval spots, about 8 of which form an oblique row from shortly without the middle of the inner margin to the costal margin 4 mm from the apex, while 7 spots are rather regularly arranged along the costal margin. Single spots in the centre of the dorsal area, an antemedian oblique band of small spots, and several dense irregularly arranged small spots in the basal half. 3 silvery spots near vein 6, the black longitudinal stripe at the base absent, hindwing somewhat darker than in *assa*. 47 mm. Length of body 26 mm. Macas (Ecuador).
- serta*. **D. sertae** *Schs.* Body reddish brown, somewhat grey at the inner and distal margins; linear transverse stripes pierced by the veins cover the wings with a great number of grey lunules shaded outward, being most numerous in the distal third of the wing. Hindwing red-brown. ♂. Mexico (Jalapa).
- usaque*. **D. usaque** *) *Pf.* (99 f). 40 mm. Smaller and darker than *assa* (99 c), more red-brown; forewing with a tiny golden dot in the basal part; a golden comma-like mark in the centre of the wing between the bands, hindwing dark red-brown, abdomen and base of hindwing bright red. I obtained this species besides others through A. H. FASSL from Colombia (Muzo, 700 m).
- sladeni*. **D. sladeni** *Hmps.* Antennae of ♂ very little dentate, the dents symmetrical; head, thorax and abdomen fox-coloured, mixed with brown. Forewing fox-coloured with numerous pale stripes and reticular markings; costal area, median area below the cell and the space between veins 3 and 6 filled with dark brown. Pale stripes form an oblique irregularly curved line from the costa before the middle as far as behind the centre of the inner margin, where it meets an oblique slightly bent line from the costa before the apex. A curved white marking composed of 2 small spots at the origin of veins 5 and 6. Hindwing red-brown, costa spotted ochreous. 34 mm. Chapadu (Central Brazil, A. ROBERTS).
- terea*. **D. terea** *Schs.* Forewing dull fawn-coloured with a slight reddish tinge. A small dark stripe at the cell-end, behind which there is an interrupted dark transverse line, besides with numerous short pale, distally brown transverse stripes. Hindwing very light red. 42 mm. Mexico: Paso San Juan. — A similar much larger form *muysca*. (80 mm) of a paler colouring and marking I got from the Chiriqui; I denominate it: **muysca** *form. nov.* (99 f).
- coscinophora*. **D. coscinophora** *sp. n.* (100 b). Size about 45 mm. Forewing dull loamy yellow, with a darker sieve-like marking. Hindwing and abdomen very dull yellowish red. Beneath as above, still duller, without any marking. From Nivac (Matto Grosso).
- obliquestrigata*. **D. obliquestrigata** *Strd.*, according to the figure, seems to be allied to *olivescens*, but lighter, more reddish brown, most of the interior area light greyish, hindwing more ochreous, feebly red towards the base. Expanse of wings: 52 mm. Length of body: 27—28 mm. From Peru and Ecuador (Upper Madre de Dios and Macas).
- olivescens*. **D. olivescens** *Pf.* (99 e). Size of *assa* (99 c). Forewing olive brown, watered silvery grey at the base at the inner margin and in the distal area. 3 rather parallel steep transverse lines on the costa, the last very much bent outward and shortened. Abdomen and hindwing coffee-brown. Received from A. H. FASSL, from Sosomoco (Colombia), 800 m. 1 specimen, 52 mm.
- trilinearides*. **D. trilinearides** *Pf.* (99 c) resembles *olivescens*, but the thorax and forewing bright red-brown, the stripes more oblique, the last not bent and shortened. Hindwing and abdomen light cinnamon red. 47 mm. Sosomoco (Colombia). From A. H. FASSL. 1 specimen.
- vibicata*. **D. vibicata** *Pf.* (99 c) resembles *trilinearides*, but the thorax and forewing pale yellowish grey, the 3 transverse lines distinctly defined, like raised streaks; abdomen and hindwing very pale reddish ochreous. 38—48 mm. Sosomoco, 800 m. By A. H. FASSL.
- michaeli*. **D. michaeli** *Pf.* (99 d) resembles *vibicata* in its colouring, but much paler; lines indistinct. More than twice as large. Thorax and forewing very pale yellowish grey, hindwing and abdomen very pale reddish in the ♂, tinged with yellowish in the ♀. 2 specimens from the Chanchamayo (1000 m), 1 from the Upper Amazons, received from OTTO MICHAEL. ♂: expanse 78 mm, length of body 37 mm. ♀: expanse 96 mm, length of body 48 mm.
- cuprifera*. **D. cuprifera** *Pf.* (99 f). 88 mm. Robust; body relatively short, head, thorax, legs and forewing copper red, the lighter transverse bands partly filled with blackish streaks. Hindwing dull copper brown, somewhat diaphanous, abdomen dull brown; under surface brown, costa of forewing spotted light. Peru (Coll. STAUDINGER).
- manoa*. **D. manoa** **) *Pf.* (99 d). A ♀ of this new prominent species which I place to *Dalaca* for the present (others range it among *Phassus*) I received from FASSL who captured it in February 1911 near Villavicencio in Eastern Colombia at an altitude of 450 m. Expanse of wings: 112 mm. Length of body: 62 mm. The forewing

*) Usaque: title of the Indian rulers of Colombia.

**) Fabulous Indian empire = Eldorado.

exhibits the marking of *Dalaca*, from the *assa*-group perhaps. Very light brownish cinnamon with light brownish olive bands and spots. Body and hindwing darker cinnamon, antennae short. — The parcel in which this lepidopteron was sent to me contained also a little bottle with the very abundantly deposited eggs. The egg is globular, glossy black and has a diameter of hardly $\frac{1}{2}$ mm.

D. subfervens *Btlr.* ♂ variable, forewing golden light red-brown, with a slight reddish lustre, smoke-*subfervens*. brown markings, brownish ochreous with subsequent red-brown markings. Costa with a series of mostly rounded spots partly pupilled black; a broad very irregular band from the base along the median vein to the centre of the disc, filling the basal half of the median area and uniting, towards the other end, with a series of obliquely confluent patches extending in a decreasing series to the costa. This band shows black spots and lines; its basally extended part projects from the inner margin in a rather large oblique black patch above which the margin is golden, light red-brown, coherent with a similarly coloured distal margin. Submarginal and marginal rows of black dots. Fringe pale red-brown. Hindwing pale dark smoky grey, fringe light red-brown. Thorax dark brown, antennae light red-brown, abdomen pale greyish brown. Under surface grey, body beneath dingy white, legs somewhat reddish. 32—38 mm. The ♀ has more red forewings with less distinct markings, and more bluish grey hindwings. Thorax redder than in the ♂. Abdomen darker. 47 mm. Chile (Las Zonas), February.

D. pallens *Blch.* is closely allied to *subfervens*. Forewing greyish brown marbled with white spots on *pallens*. which there are black dots. Chile.

D. violacea *Btlr.* This and the following species are likewise from Chile. Forewing of ♂ slate-grey with *violacea*. a violet gloss, a costal spot as in *subfervens*; a small irregular light red-brown spot in the centre of the disc, above which there are 2 brown spots. An irregular shortened dark brown longitudinal line with a chestnut red upper margin and a pale yellowish lower margin. A few black spots along the distal margin. Fringe reddish brown. Hindwing greyish brown with a bronze lustre, antennae smoky brown; abdomen greyish brown, with silky hair. Wings beneath greyish black with sandy yellow fringe, forewing with a sandy yellowish or brownish costal margin with 1 or 2 black dots on it. Body beneath whitish. 1 ♂. Expanse of wings: 32 mm.

D. marmorata *Btlr.* Forewing creamy, divided by intersecting greyish brown bands into spots and pieces *marmorata*. on which there are black markings. Hindwing grey, 2 black subapical spots; fringe creamy; thorax blackish brown, paler in the middle; head and antennae smoky brown, abdomen greyish brown. Basal segments and markings whitish. Wings beneath greyish brown, silky, basal part and fringe pale blackish brown; ventrum whitish. 32—37 mm. Chile, taken in February.

D. venosa *Blch.* (= *nigricornis* *Wkr.*). ♂ tortoise-coloured, forewing brown with white partly confluent *venosa*. stripes. Hindwing somewhat darker, base paler, fringe white. Length of body: 8—9 mm; length of wings: 23 mm. Chile.

D. hemileuca *Btlr.* is well discernible by the bipartition of the colour on the forewing. ♂ forewing silky *hemileuca*. brown, almost black at the costal margin as far as $\frac{2}{5}$ of its length, a large spot occupying almost the whole inner margin the same. The rest of the wing very light silky brown. A small light red-brown spot in the apical third. Below it 2 oblique silky grey spots, and from the lowest 3 similar ones upward to the apex. An oblique whitish brown stripe divides the exterior end of the dark spot at the inner margin. Hindwing greyish brown, paler at the base. The ♀ is larger and paler. The light and dark areas less contrasting. 30—41 mm. Chile.

D. fusca *Mab.* (185 b). 27 mm. Taken by Dr. HYADES at the Orange Bay, Chile. Blackish brown; fore-*fusca*. wing intensely brown, reddish at the base, a grey macula in the middle with two black dots, and a broad ante-marginal band. One ♂. — A probably closely allied species I received from Chile. I found it nowhere described. 30—40 mm. Brown, marking very variable, forewing with a black basal ray at the inner margin and 2 light, dark-edged, more or less visible maculae. The distinctly marked specimens show a Noctuid-like habitus of the forewing. According to 8 specimens. Valdivia. I denominate the species: **noctuides** *sp. n.* (99 e). *noctuides*.

D. mummea *Schs.* Very light grey with a paler exterior and submarginal band, the latter composed of *mummea*. coherent square spots. 40 mm. Petropolis (Brazil).

D. prytanes *Schs.* Forewing greyish brown with a few white stripes along the costa; a short oblique *prytanes*. dark brown basal stripe bordered with whitish; a dark brown shadow, enclosing a few small silvery spots, from the end of the cell to the interior angle; a brownish submarginal transverse band, darker, as far as it touches the above mentioned shadow; besides, the forewing is crossed by indistinct transverse lines. Hindwing and body brown, brownish beneath, the costal margin loamy yellow with dark brown spots. 33 mm. Petropolis.

D. oreas *Schs.* Forewing dark brown, indistinctly marbled, with slightly pale lines; a small dark shadow *oreas*. and 2 tiny silvery spots above the cell. An exterior dark transverse line and 3 silvery spots at the distal margin below the apex. Hindwing and thorax velvety brown, abdomen brown. Under surface dark brown. 43 mm. Petropolis.

- verresi*. **D. verresi** Schs. is somewhat similar to *oreas*. Thorax and abdominal end brown, the base cinnamon brown. Forewing brownish grey, darker at the costal margin and at the apex, with white spots before the latter at the costal margin. An oblique silvery brown-edged luna in the cell near the base. A triangular brown spot in the cell-end is divided by an oblique silvery line, below it interrupted extending obliquely inward. An ochreous spot below the cell-end. Exterior band pale brownish grey, bordered outside by a dark line, parallel to the margin. From this line a broad white horizontal stripe between vein 5 as far as above vein 6. Hindwing brown or cinnamon brown. ♂ 35 mm. Sa. Catharina.
- basirubra*. **D. basirubra** Schs. Head and thorax dark brown, lighter behind, abdomen brown, with long red hair on the dorsum. Forewing dark grey, shaded dark brownish ochreous between the subcostal and median vein. A small golden spot near the base of the cell, three similar ones at the origin of vein 6. A few similar scales above the bar between veins 2 and 3; an exterior row, a subterminal one and a marginal one of dark and ochreous brown spots, the exterior row shaded light ochreous between 4 and 7; two dark velvety brown spots above vein 1b, bordered with grey behind. Hindwing light brown, with long red hair at the base. 80 mm. Peru.
- tesselloides*. **D. tesselloides** Schs. Body and forewing pale brown, the cell and the space between the veins uniformly filled with double dark stripes forming incomplete rings edged with tan-colour; a line behind the cell from vein 4 to 7, inwardly shaded with tan-colour. Hindwing from light red to brown. 62 mm. Paraguay. — Here a form may be inserted from the Coll. SEITZ, showing predominantly tan-coloured forewings with darker markings.
- stigmatica*. Size 55 mm. We denominate it: **stigmatica** sp. n. (100 b).
- guarani*. **D. guarani** Pf. (100 b). Expanse of wings: 62 mm, body 35 mm. Forewing tan-coloured, all the veins distinctly visible. Strewn with rows of tiny white-granulated dots in the distal part and at the margin. Hindwing pale light red. Beneath as above, without any marking. Body tan-coloured, reddish in the central part.
- katharinae*. From Sa. Catharina, Brazil. — From the same district I received an allied though very small species: **katharinae** Pf. 30 mm. Forewing intensely darkened except the distal part, dots very indistinct, hindwing light red.
- thisbe*. **D. thisbe** Drc. Head, antennae, thorax and abdomen dark brown, abdomen beneath yellowish brown, legs darker; forewing yellowish brown, darkest along the costa; a metallic golden spot at the inner margin near the base; a series of metallic golden spots cross the wing behind the middle, from the costa to the inner margin; 2 golden postcellular spots and a marginal row of gold spots from the apex to the anal angle. Fringe brown; hindwing uniformly pale brown. 38 mm. Colombia (Don Amo). — An evidently closely allied form was sent to me by FASSL from Sosomoco, Eastern Cordilleras of Colombia (800 m); the main difference is that the rows of spots do not reach the costa, but extend only to the centre of the wing. 35 mm. It may be called: **hemichrysea** form. nov. (99 g).
- saguanmachica*. **D. saguanmachica** Pf. (99 g). 2 specimens are at hand, expanse 30 and 39 mm. Dark brown, the rings oblong, in rows; a tripartite silvery-golden marking in the centre of the forewing; the smaller specimen with another one, half way to the distal margin. Hindwing dark brown, margin brownish ochreous; body dark ochreous, under surface brownish ochreous, all the margins of the wings ochreous. From the Eastern Cordilleras of Colombia (Buena Vista, 1200 m). A. H. FASSL.
- fasslii*. **D. (? Triodia) fasslii** Pf. (99 f). 2 ♂♂, 1 ♀, received from FASSL from Sosomoco, Colombia, 800 m, and Villavicencio, 450 m. At the latter place he captured a couple in copula, which had flown from the direction of the Llanos to the carbid-light and were thus captured. Expanse of wings of ♂♀ 35 to 52 mm, length of body: ♂♂ 20—22 mm, ♀ 34 mm inclusive of the anal tuft. ♂ ochreous brownish grey, a broad whitish stripe from the base into the anal angle. The forewing is crossed by transverse rows of indistinct rings. A tiny silvery stigma at the cell-end. Hindwing and abdomen brownish ochreous. ♀ dark grey with a slight dark violet lustre, especially on the hindwing. Forewing filled with brownish ochreous in the middle, the whitish patch very indistinct; marbled with rows of rather round dark greyish brown ring-spots, instead of the silvery stigma a dark spot in the cell. Thorax greyish brown, abdomen with a violettish black lustre. Marking similar to that of *saguanmachica*, but colouring different.
- tapuja*. **D. tapuja** Pf. (99 e). Smaller, lighter; forewing dotted dull yellowish black, especially at the costal margin. A small black spot at the cell-end, a larger one above the inner margin. Southern Brazil (Leopoldina). 1 specimen from Coll. SEITZ.
- cocama*. **D. (? Triodia) cocama** Pf. Expanse of wings: 43 mm, length of body: 25 mm. Forewing dull tan-coloured, a black dark median shadow, otherwise marked by black comma-like streaks forming loosely indicated transverse rows. Hindwing greyish brown, bordered with ochre; body yellowish brown, posterior half of abdomen yellowish. All the wings beneath brownish ochreous. North Peru (Huancabamba), 6400 ft. — Very closely allied is: **D. niepelti** Pf. *). ♂♀ 59—62 mm. Expanse of wings: 34—39 mm. ♂ forewing yellowish brown, the space between the veins with dark comma-streaks, a silvery stigma at the cell-end on a darker ground. Hindwing earth-coloured with an ochreous margin, head, thorax and end of abdomen earth-coloured; the middle of the abdomen lighter. Under surface smoky brown, all the wings with an ochreous margin, ♀ stouter, wings

*) Described and figured in the Rhop. Niepeltiana, p. 59, pl. XI 14.

rounder and broader, darker brown, forewing with broad dark transverse shadows from $\frac{3}{4}$ of the costa to the inner margin, without a stigma. Costa marbled dark. The comma-like markings are united forming indistinct, irregularly defined circles. Thorax, head and antennae dark brown; hindwing and abdomen earth-coloured. Fringe brown. Under surface smoke-brown, abdomen and costal region of forewing yellowish brown. From Macas (Ecuador). — Another tiny Hepialid form belongs to this place; it was sent to me by FASSL likewise from the Eastern Cordilleras. I denominate it: *D. (? Triodia) nannophyes form. nov.* Expanse: 22 mm. Length of body only 13 mm. The much rubbed forewings merely exhibit an originally dark brownish ochreous ground-colour and to the left a silver central stigma. Hindwing darker brownish grey, margin brownish ochreous, body greyish brown, thorax, head, antennae more brownish ochreous. From Sosomoco. 800 m. — 1 specimen (type); it is not well enough preserved for being figured, the marking being quite extinct in some places. *nannophyes.*

D. (or gen. nov.?) **perkeo** Pf. (99 g) is likewise a somewhat doubtful tiny species which I range here provisionally. FASSL sent it to me from the Eastern Cordilleras of Colombia. He captured it on the Paso del Quindiu (3800 m), where he observed the ♀♀ depositing their eggs on the grass in the midday-sun; unfortunately, only two badly preserved specimens were sent. Expanse of wings: 25 and 27 mm; length of body: 14 mm; antennae 5 mm. Forewing dark reddish ochreous, with blackish oblong dots and strigae. Hindwing diaphanous grey, fringe everywhere broadly dark brown, body dark brownish grey, anal angle of forewing not rounded, but distinctly with an obtuse angle. The habitus of the insect resembles that of certain *Tineidae* which FASSL sent me from the same locality. *perkeo.*

4. Genus: **Triodia** Hbn.

Allied to the preceding ones, antennae longer, abdomen very long. Living in the High Andes.

Tr. monticola Mssn. (185 b). Length of body: 18 mm, length of forewing: 18 mm. Head and thorax dark greyish brown, antennae ochreous, abdomen yellowish grey, projecting far beyond the hindwing. Forewing dark greyish brown, with a white inner-marginal stripe from the base to the centre, from where it extends to the apex of the wing as a band broken up into spots. These spots exhibit dark rings in the middle, and their colour is light grey. Between this band and the distal margin there is yet a fine row of white dots, and between the latter and the base a light yellowish grey stripe with a dark ring in it. Hindwing grey, yellowish grey at the inner margin. All the fringes brownish grey. Under surface unicoloured brownish grey, yellowish grey at the interior angle of the hindwing. Very variable, sometimes with hardly any marking. Ecuador (Sincholaguar), 4200 m. Swarming in great numbers in a November night. Habits similar to those of the palaearctic *Hepialus hectus*. *monticola.*

Tr. lucicola Mssn. (185 f). Length of body: 22 mm, length of forewing: 20 mm. Similar to *monticola*, somewhat larger, much lighter, more yellowish grey, the band of spots more ochreous, based to it several such spots; the white dots between the band and the distal margin indistinct, because the distal margin in its whole extent is almost as light as the band. Fringes of all the wings ochreous. Under surface unicoloured brownish grey. Fringes ochreous speckled with brown. Ecuador (Putzulagua near Latacungo). 3600 m. Like the following *remota*, it may be merely a local form of *monticola*. *lucicola.*

Tr. remota Pf. (99 e). Size 45—46 mm. Body very long (23—25 mm) and slender, dark brown, antennae long (7—8 mm). Forewing: ground-colour dark ochreous, marbled lighter, the long fringes speckled. The scheme of markings resembles that of *H. sylvinus* the triangular marking is light flesh-coloured, broad, intense, distinctly edged with dark. Parallel to the distal margin a double row of fine irregular rings partly centred silvery in the apex. Hindwing light ochreous, less dusted towards the base, fringe unicoloured brownish ochreous. Under surface: light ochreous. From Challabamba, Peru, at an altitude of about 4000 m. Types (2 specimens, one of them much damaged) in the Coll. PFITZNER in the Museum Senckenberg in Frankfurt on the Main. *remota.*

5. Genus: **Pielus** Wkr.

Antennae strongly pectinated. Robust, of a Bombycid-like habitus. The most magnificent representatives of the genus occur almost exclusively in Australia; merely one relatively small species in America.

P. luteicornis Berg (99 h). Thorax greyish brown, abdomen intensely covered with ochreous hair. Antennae brownish ochreous. Wings hyaline, diaphanous, forewing brownish ochreous, with whitish markings, hindwing lighter, costa ochreous. 45—55 mm. My series comprising about 20 specimens shows that the species does in general not vary much. — However, there occurs, without any transitions, a form without any markings, similar to *Hep. gallicus*. I denominate it **popperi** form. nov. (*luteicornis* was formerly ranged as “*Hep. popperi popperi* i. l.”). Patagonia, Fuegia, and particularly at the Magellan's Str. Taken near Punta Arenas from March 13th to 17th (flying about in especially great numbers after a cyclone); Rio Grande, Eastern Fuegia, in February. *luteicornis.*

6. Genus: **Callipielus** Btlr.

Neuration very similar to that of *Pielus*. Wings shaped as in *Charagia Wkr.* (Vol. X, p. 828), broad, forewing triangular, costa rather straight, apex obtuse, exterior angle rather uniformly rounded. Body very long, rather thin, thorax long-haired, antennae short, thin. Legs rather short and stout.

arenosus.

C. arenosus Btlr. (185 e). Habitus similar to that of *Pielus australis Wkr.* (Vol. X, pl. 77 b). Forewing pale flesh-brown, clouded dark, very scantily watered with pale yellow, covered with irregular silvery dots and spots which are bordered with dark brown. A submarginal silvery stripe bordered with brown does not reach the costa. A marginal series of small oval silvery spots bordered with brown; a silver streak bordered with black through the cell; sometimes 1 or 2 black streaks at the discocellular veins, and a series of oblique discal streaks before the silvery submarginal stripes. Hindwing sandy ochreous. Under surface everywhere sandy ochreous. 78—81 mm. Chile (Valdivia). A beautiful series of this rare species is in the Berlin Museum, from which we have figured a specimen here.

7. Genus: **Philanglaus** Btlr. *).

Habitus of the *velleda*-group, but the antennae pectinated as in the Australian genus *Porina* from the *Oxycanus*-group. Forewing truncately triangular, veins uncommonly plain. Hindwing almost triangular. Apex rather pointed, thorax very robust, head short, palpi short and stout, not projecting beyond the head. Antennae rather long, of $\frac{2}{5}$ of the length of the forewing, pectinated. Abdomen rather broad at the base, compressed behind, legs rather long and stout.

ornatus.

Ph. ornatus Btlr. Forewing of ♂ above white in the costal area, the oblique area, crossed by the median vein and the radial veins, greyish brown, exterior and interior parts pale sandy brown with distinctly marked dark brown markings edged snow-white: 2 basal spots, 1 irregular transverse spot, from the base of the costa to the exterior third of the inner margin, its centre almost square, separated by a white edge from an indistinct semicircular spot at the basal third of the inner margin. Two small darker spots before the centre of the costa; the oblique band passes through the cell-end; 2 or 3 small dark spots at the disc and a light irregular discal band. Fringes traversed by 2 pale brown lines, a white line between them. Hindwing pale silky sand-brown, a feebly undulated dark postmedian line, fringes as on the forewing. Thorax whitish brown, striped grey, collar white with a brown spot on each shoulder; head brown, vertex white; antennae white, pectinations brown, abdomen greyish white. Under surface pale sand-brown with brown bands. The markings of the upper surface show through beneath. Hindwing bordered with white at the curved part of the costa, a black spot behind it, a bipartite costal spot and a triangular apical spot, fringe with a pale basal line, bordered by a grey line, behind which there are 1 or 2 white spots. 55 mm. Chile.

8. Genus: **Osrhoes** Drc.

Head very small, palpi short, long-haired, the 3rd joint very tiny. Antennae very short, thorax, abdomen, legs slender. hindlegs of ♂ with dark hair. Forewing long, very round at the anal angle, cell long, narrow; hindwing long, narrow, apex rounded.

coronata.

A. coronata Drc. ♂. Head, antennae, collar, palpi and thorax golden brown, abdomen and legs dark brown. Forewing golden brown, hindwing pale brown, all the fringes brown. ♀: forewing dark brown, with some very indistinct dark brown maculae at the inner margin. Distal margin from the apex to the anal angle watered with grey scales. Both sexes with an expanse of wings of 33 mm. Colombia, Sierra del Libano.

9. Genus: **Phassus** Wkr.

This highly specialized genus is most characteristic of Tropical America, where it reaches the climax of its development, while the other centre of development, the Indo-Australian Region, is far inferior both in number and size of the species. Antennae very short, thin, palpi disappearing, proboscis absent. Abdomen very long; wings broad, separated far from each other (the Hepialid gap), apex of forewing extended. Marbled brown and grey, more or less spotted golden. From medium sizes to gigantic sizes. Larvae in the trunks of trees. Distributed throughout Tropical and Subtropical America.

eldorado.

Ph. eldorado Pf. (99 g). Expanse of wings: 53 mm. Thorax brownish ochreous. Abdomen reddish ochreous. Forewing with a sharp falciform apex. The scheme of markings generally similar to that of *Ph. shamyl* (Vol. II, pl. 54 a) to which the new species appears to be most closely allied, but the ground-colour of the forewing is not brown, but of a bright brown gloss. As in *shamyl*, there is a macula in the discal area and a series of 4 small ones before the costal margin; they are of a lighter golden colour than the ground (silvery golden).

*) The species *ornatus* dealt with here by PFITZNER is probably better ranged among the *Cossidae*.

Before this series of spots, at about $\frac{2}{3}$ of the costal margin (counted from the base), begins a dull flesh-coloured transverse band 2 mm broad, parallel to the distal margin; a similar golden brown interrupted spot is in the apex, 3 others, likewise intermixed with brown, at the costal margin between the base and the transverse band. A dull flesh-coloured blotch extends at the inner margin from the base to the end of the transverse band, with which it rather indicates than represents the well known triangular Hepialid marking. Hindwing of a bright reddish ochreous colour in the distal part, in the anterior part duller, darker, semidiaphanous. From Venezuela (Merida), 1 ♂ in my collection. Denominated according to the legendary "man of gold" (el dorado) whose home was in the same district.

Ph. aurigenus Pf. (99 h). Likewise an isolated species. Expanse of wings: 64 mm, length of body 36 mm. *aurigenus*. Thorax, abdomen and antennae dark brown. Forewing grey, costal half beautifully reddish ochreous, anal half beautifully marbled dark brown. 3 groups of intense golden spots (on the basal part, in the centre and apical part). Hindwing grey, apex and base and the adjoining parts of the body yellowish ochreous. Under surface brownish grey, diaphanous, edged with a bright ochre. 1 specimen from the Orosi, Costa Rica, 1200 m. Type in my collection (Museum Senckenberg in Frankfurt on the Main).

Ph. absyrtus Schs. ♂ light red-brown, forewing behind the middle traversed by 4 darker brown bands from the costa to the median vein; darker shadows and lighter undulated stripes around the interior angle and along the inner margin. ♀ with more indistinct bands traversing the whole wing. 60—85 mm. Brazil (Petropolis). *absyrtus*.

Ph. agrionides Wkr. ♂ brown, antennae yellowish brown, abdomen somewhat paler than the thorax, projecting far beyond the hindwings, pale brown, darker at the apex. Forewing slightly cancellated, numerous eurved transverse stripes between the veins; stripes paler on the inside, darker outside. Length of the body: 25, length of the wings: 50 mm. Brazil. *agrionides*.

Ph. pedipogon Strd. Similar to *triangularis* H.-Edw. Colour of forewing likewise similar, but the base at the inner margin of the forewing and the base on the hindwing with pinkish red hair. At the costal margin also small black spots, more distinct. A light spot at the costal margin near the base, edged with black, resembles the same in *hübneri* (100 c). At the same distance at the costal margin another similar light spot, and a quadrangular spot behind it. The exterior light band extends indistinctly to vein 3. Submarginal band light grey, irregular, similar to that in *triangularis*, with a brass-coloured dot above vein 6. A narrow light band extends from the second spot at the costal margin inward as far as vein 2, a brass-coloured dot below it. Base and interior area as in *triangularis*. The silver spot at the cross-vein is replaced here by a brass-yellow similar spot. Hindwing similarly streaked outside at the costal margin as in *hübneri* (100 c), such streaks also at the distal margin. 126 mm. 1 specimen from Costa Rica. *pedipogon*.

Ph. triangularis H.-Edw. This well-known large species, with its subordinate forms and allies, has a rank in America similar to that of *Ph. signifer* and its allies in the Indo-Australian Region. The range of the *triangularis*-group extends from Mexico across the whole of Central America to the Isthmus of Panama. *triangularis* is from greyish brown to yellowish brown; recognizable by the thick brown triangle in the centre of the forewing, at the upper end of which in the cell there is the silver stigma. Body very long, blackish brown, lighter ringed. 96—160 mm. SCHAU reports about its biology: eggs of 3—5 mm diam. Very numerous, at first grey or blue, then brown or black with a sticky coating. The ♀ drops them at random into the underwood. Larva 10 cm; head large and very strong, well withdrawn beneath the strong broad dark brown second segment. The third segment like old ivory, the fourth has 3 such spots, the rest of the body dark velvety brown, a large ivory yellow oval spot on each ring, one small accessory spot each on the 5th and 6th; a small round ivory spot on the sides behind the stigmata, and an ivory line below it. The last segments quite brown. The larva bores a passage almost 3 feet long into the roots of trees, so that often only the outward bark of the root is left. The outlet near the surface of the earth is covered with a hard web of silk and refuse. Before the metamorphosis it spins a silky cover exactly fitting into the opening. On lifting this cover one notices neither a larva nor a pupa, because the insect immediately disappears below on its being disturbed. Pupa almost just as mobile as the larva. The tree the roots of which it inhabits is called "Guzamillo" by the Mexicans ("magot-tree" in English), the Hepialid living in such great numbers in it. It emerges between 3 and 5 p. m. However common the larva is, yet the imago is but rarely found. Nearly all the specimens in the collections were bred. — An allied form from Mexico is: **triangularides** Pf. (100 c). Markings quite indistinctly brownish ochreous, rather unicoloured, without a silver stigma. There are also intermediate forms between this form and *triangularis* with a slightly traceable triangular marking, and numerous transitions. — Of the form **hübneri** Geyer (= *Pharmacis hübneri* Hbn.) (100 c) I received 1 specimen with this label by LÜCK & GEHLEN; it is recognizable by the rosy red hair on the bases of the wings and of the abdomen. Forewing with golden stigmata in a brown triangle and at the apex. 122 mm. 1 specimen from Orizaba (Mexico), August 1909. This form is a transition to the following species: *triangularides*. *hübneri*.

Ph. rosulentus Weym. Greyish brown, marbled by small short light grey transverse striae. 3 darker spots at the costa. Silvery markings at 1 b, at the cell-end, at veins 4, 6, 8 and 9. Hindwing pale rosy red at the base *rosulentus*.

as far as $\frac{1}{4}$ of the costa and the centre of the inner margin, otherwise greyish brown. Inner margin with rosy red hair. Its habitus somewhat similar to that of *Ph. regius* from Tibet (Vol. II, pl. 54 b), but it is much larger (expanse of ♂: 87 mm). Mexico (Jalapa).

n-signatus.

Ph. n-signatus Weym. Whitish grey, partly brownish yellowish grey. Chiefly recognizable by the thick silvery dentate line at the end of the anterior part of the cell, about 5 mm long, N-shaped. The single streaks of this figure are about 1 mm thick, edged with dark brown. Towards the inner margin a pear-shaped olive brown spot, 9 mm long and 5 mm broad; a similar larger one towards the base on vein 3. The rest of the surface on the forewing is covered with greyish brown undulate transverse lines. Hindwing dark greyish brown, light ochreous at the apex. Expanse of ♀: 150 mm, length of body: 69 mm. Distinguished from *triangularis* by the differently shaped brown spots, the differently shaped silver mark, the dark angular markings at the distal margin, and the almost straight costa; from the following *marcius* by the marks mentioned above and besides by its considerable size and the absence of golden spots. Guatemala.

marcius.

Ph. marcius Drc. (100 a) forms the transition to the *argentiifera*-group. Forewing pale greyish brown, densely marked with grey and darker brown lines, a double row of blackish brown oblong spots, from the costa near the apex to the inner margin, and a series of oblong bent lines around the distal margin from the apex to the anal angle. A rather long golden stripe broken up into 3 spots, at the cell-end; 2 tiny golden dots towards the distal margin; hindwing pale greyish brown, palest at the base, a few darker maculae at the costa near the apex; head, thorax and abdomen pale greyish brown; expanse: 105 mm. Mexico, near Durango. — Another *Phassus* of my collection presumably belongs to this group, being conspicuous for its monotonous exterior. Expanse of wings: 100 mm, wings dull greyish brown, forewing indistinctly marbled by somewhat lighter and darker lines. In the cell an irregularly defined silvery stripe 9 mm long, parallel to the inner margin, in the prolongation of its direction two little dots situate close together; the marking is somewhat different on the two halves of the wings, more articulate to the left than to the right, 3 small dots against 2, the longitudinal stripe pierced, bipartite. I denominate this species for the present as: **exclamationis** sp. n.

exclamationis.
costaricensis.

Ph. costaricensis Drc. (185 c). Size: 82 mm, found in Costa Rica (by PLATEN). Almost unicoloured dull yolk-coloured, with fine dark streaks, a black spot at the cross-vein and a fine exterior line. The body with light brown hair.

argentiifera.

Ph. argentiifera Wkr. (100 c). Beside *triangularis* the best known American species. Much smaller (65 to 75 mm), more ashy grey, less distinctly marked. 2 silvery spots at the costa, 3 in the disc. Mexico, Costa Rica (Irazu, 6000—7000 ft.); Panama (Chiriqui 2000—3000 ft.). *hübneri* which we likewise figure on pl. 100 c is more intensely reddened, more contrasting, perhaps more similar to *argentiifera* than to *triangularis* where it is already mentioned.

basirei.

Ph. basirei Schs. (100 a, as *triangularis*). Separated from *triangularis* by the different incoherent shape of the triangular marking; the species designed as *triangularis* on pl. 100 a is in reality *basirei*. From Mexico.

phalerus.

Ph. phalerus Drc. (185 f) is a larger species (100 mm) from Mexico; Guatemala (Purala, 4000 ft.). Easily recognizable from the figure.

trojesa.

Ph. trojesa Schs. (100 d). Head and thorax black, behind with pale leather-coloured transverse lines. Forewing grey, striated black, basal third from vein 1 b broadly marbled white; an oblong black spot below this vein at the base; a white spot at the cell-end, close at vein 6; a brownish median shadow from the cell-end to vein 1 b, between which and the median vein it is very dark; a broad brown subterminal band curved outwards between veins 5 and 8; distal margin and fringe dark brown with triangular paler dots. A few white shadows before the apex; costal margin with darker spots. Hindwing greyish brown, light brown hair at the base, fringe light brown, 2 dark spots at the apex. 70 mm. Mexico (Trojes).

smithi.

Ph. smithi Drc. (185 d). Forewing pale fawn-coloured, indistinctly marbled with darker shadows; few lunar spots at the apex and distal margin. Hindwing uniformly reddish fawn-coloured, slightly striped and paler towards the apex; under surface everywhere pale fawn-coloured. Head and thorax reddish fawn-coloured, abdomen and legs pale fawn-coloured, antennae brown. 110 mm. Mexico (Atoyac, Veracruz). Taken by H. A. SMITH; 1 specimen in May 1888. — A closely allied species is **Ph. championi** Drc. (185 d), from Guatemala. Forewing pale reddish yellow, densely striated dark. Small blackish brown spots close at the costal margin, a few also at the inner margin near the base. Hindwing dark brown, lighter brown at the apex and narrowly so at the margin. 150 mm. Described from 1 ♂ from Guatemala.

championi.

umbrifera.

Ph. umbrifera Fldr. (185 f). 75 mm. Body greyish brown. Forewing grey. An irregular silvery band from the centre of the cell towards the apex, extending to $\frac{2}{3}$ of the length of the wing. A similar submarginal band from the apex to vein 2. Hindwing red-brown, narrowly grey at the margin. Brazil.

modestus.

Ph. modestus H. Edw.*). Size 60 mm, body 22 mm, projecting by $\frac{1}{3}$ beyond the hindwings. Shaped

*) A. species *modestus* H. Edw. exists only as a synonym of *Hep. hectoides* (p. 1290). There is also a label inscribed *Phassus modestus* in the Berlin Museum near *Call. arenosus*, but the specimen is missing. It was presumably wrongly determined before. Which species PFITZNER had in view can no more be ascertained.

like *Callipielus arenosus* (185 b), rather robust. Forewing yellowish ochre, tinged with orange. One sharply defined light longitudinal blotch each at the costa and inner margin. The 4 blotches together form a saltier the arms of which extend to half of the costa and inner margin. Hindwing brown, margined with yellowish ochre; thorax, head and legs yellowish ochre. Body and wings beneath yellowish ochre. According to one specimen in the Berlin Museum. South America.

Ph. giganteus H.-Schäff. (100 d) is the largest of all the American *Hepialidae* and one of the largest *Hetero-* *giganteus*. *cera* altogether. The ♂ of my collection has an expanse of 130 mm, the 4 ♀♀ vary from 150 to 200 mm, though there may occur even larger specimens. Dull orange or tan-coloured, the ♂ with darker median shadows and a silver stigma in the cell. Southern Brazil (Sa. Catharina) and Paraguay. — The very closely allied **Ph. hayeki** *hayeki*. *Fötterle* (185 b), from Petropolis, may be only a subspecies or local form; median area of the forewing dark brown with lighter costal spots. A double row of brown, light-edged oval spots at the inner margin of the forewing; sometimes they are also absent or indistinct.

10. Genus: **Pseudophassus** Weym.

The 4 or 5 representatives of the *momus*-group form a well defined genus (perhaps also only subgenus), recognizable by the robust habitus and the strong antennae, as well as by the distinctly marked dark, light-edged trapezoid spot at the lower end of the triangular marking close above the middle of the inner margin. The scheme of markings resembles that of *excrecens* from Japan (Vol. II, pl. 54 a, as *herzi*).

Ps. momus Drc. (185 e). Abdomen and base of hindwing more or less red. *momus* Drc. has fawn-coloured *momus*. forewings, with dark red-brown bands at the costal margin and a large reddish brown triangular spot below the cell-end. A reddish white band crosses the wing at the cell-end and expands at the inner margin; a series of brown marginal spots from the apex to the anal angle. Hindwing fawn-coloured, almost red at the base. Body reddish brown; antennae and legs darker brown. 64 mm. Peru (Sarayacu). FASSL sent me from the Rio Songo (Bolivia) an allied form with a partly very bright vermilion abdomen and base of the hindwing. It is the form denoted by WEYMER as **metricus** (Weym. i. l.) *form. nov.* (99 h). The red-tinged subspecies I denominate: **songoensis**. *metricus*. *songoensis*. There are much more intensely coloured specimens. Described according to 7 specimens from the Rio Songo. 45—65 mm. — **metellus** Drc. (99 g) is mostly without any red, more yellowish brown, a golden stigma in the *metellus*. cell, antennae and legs black. Size of *momus*. Peru (Sarayacu, Upper Madeira, Chanchamayo).

Ps. prosopus Drc. Body reddish brown, forewing pale reddish fawn-coloured, marbled darker, interior *prosopus*. part near the base reddish. 3 interrupted greyish bands traverse the wing behind the middle from the costa to the inner margin, fringe dark brown, hindwing pale reddish brown. Expanse: 75 mm. From Colombia (Bonda).

Ps. mahagoniatus Pf. (99 h). 36—43 mm. The ♂ dark mahogany red-brown, shaded dark red-brown *mahagonia-* *tus*. in the distal half. A triangular marking in the median area, similar to that of *triangularis*, very distinct, dark red-brown, a silver stigma in the cell. Body dark brown, abdomen and base of the hindwing with reddish hair. ♀ larger, duller, without a reddish tinge (violetish brown). Marking of forewing blackish brown. Hindwing transparent at the base, without any red. Base of abdomen with very pale reddish ochreous hair. A couple captured by FASSL on the Rio Songo in 1912.

Family: **Dalceridae.**

By Dr. HERBERT SICK.

This family established by DYAR is closely allied to the *Limacodidae*. It ought to have been placed right after them, but it was omitted by mistake and is now appended here. It is a small family of mostly unicoloured yellow or whitish species occurring almost only in the neotropical faunistic region, very few species advancing also to the North American region. They are species with roundish broad wings, short pectinated antennae which are less strong in the ♀. Palpi small, proboscis rudimentary or absent. A few species bear tufts of scale-hairs on the antennae, particularly conspicuous in *Dalcera abrasa* whose antennae are covered with rows of longitudinally arranged white scales which, however, are very loosely attached and fall off rather easily. They seem to be scent-organs occurring in both sexes.

The biology is known in but few species. The larva of *Acraga flava* (according to BURMEISTER 1878) is almost "as long as a thumb", green and covered with several rows of tubercles which are gelatinous, colourless transparent and easily fall off on being touched. The larva of *Acraga moorei* (according to JONES 1882) is diaphanous white as if it were of "Venetian glass". The elaspers are absent and only indicated by slight swellings of the skin. The larvae creep along like snails. The pupa of *A. flava* is described to be thin and transparent, the cases of the wings and other appendages of the body are half free. Moreover, according to HOPP, the skin of the larva is almost without any elasticity, because the exterior chitinous stratum is not, or only slightly, developed. For this reason, the moult is also quite different from that of the other lepidoptera. The latter periodically cast the whole chitinous outside skeleton, whereas the Dalcerid larva moults only partly, the skin being thrust off by and by from one segment after the other, starting from the tubercles — 6 on each segment. Even the segments moult again in single sections. The tubercles shine through the cuticula shortly after the moult like small white discs, projecting shortly before it like tiny knobs. In the last stage of the moult, the tubercle peels off from the body and falls off with the part of the cuticula belonging to it. In *Acraga flava* four tubercles are coherent on one cuticular plate which is then thrust off jointly. Since one or several tubercles with their cuticular plate fall off from one segment or another, the larva is moulting continuously. As to the moult of the head or of the anal parts, no observations are known so far, but the process of moulting is presumably the same and as normal here as in the other lepidoptera. Further detailed observations concerning the larvae have been made by DYAR (Ins. Insc. Mens., Vol. XIII, 1925, p. 44—46), being the completest hitherto known. DYAR obtained larvae of *Acraga coa* from Payo Obispo, Quintana Roo, Mexico, defoliating trees in a park. The larvae are whitish ice-coloured, dotted with crimson tubercles and small black markings, smooth, with a thick transparent gelatinous skin. SCHAUS observed the larvae while collecting them at night; in the light of the lamp they looked like big drops of water. The head of this larva is round and only chitinized in its lower part, the rest included in the thorax. The oral part is well developed, with a triangular leaf-shaped spinning wart. The prothorax can be withdrawn into the third segment. Each segment bears round papillary tubercles. The large and round stigmata are situate just above the edge of the ventrum. The pupa rests in a cocoon which is simpler than that of the *limacodidae* and even that of the *Megalopygidae*. The cocoon is usually fixed to the upper surface of leaves, or between leaves.

1. Genus: **Dalcera** H.-Schäff.

Body slender, palpi thin, hardly projecting beyond the head, the second joint much longer than the first, the third small and pointed. Abdomen not projecting beyond the hindwings. Legs thin, wings broad, convex in front, rounded at the apices, rather oblique at the distal margin. Three interior veins, the second equidistant from the first and third.

- abrasa*. **D. abrasa** H.-Schäff. (185 a). Reddish yellow; antennae black, moderately pectinated, with tufts of scales apically; prothorax pale yellow, each side with a brown spot connecting the streak of the two forewings. Tarsi apically black. Forelegs partly black. Forewing reddish, pale yellow along the costa, with a small oblique discal spot; a median stripe and the distal margin brown. Colombia, Venezuela, Guiana.
- laxta*. **D. (?) laxta** Drc. Forewing brownish grey, undulate brown lines from the costal margin to the anal margin. Hindwing dark grey, palest at the base. Wings beneath grey without any marking. Antennae and legs pale brown. Head, thorax and abdomen pale grey. Closely allied to *ampela*. Ecuador, Sarayacu.
- alba*. **D. (?) alba** Drc. Forewing of ♂ white, slightly transparent, pale brown along the inner margin. Head, thorax and abdomen brownish white, antennae pale brownish yellow, legs pale brown. The ♀ is considerably larger than the ♂; forewing somewhat browner at the costal margin, but without the intense colouring at the inner margin. ♂ 13 mm, ♀ 24 mm. Mexico, Presidio (FORRER); Guatemala, Volcano of Atitlan, 2300—3500 ft.
- ampela*. **D. (?) ampela** Drc. (185 a). Forewing white, the costal half slightly hyaline; inner margin and anal angle shaded with pale brown; a brown streak right across the anal angle. Hindwing purely white, slightly shaded with brown at the distal margin near the anal angle. Head, thorax and abdomen pale yellowish brown. Head and antennae somewhat darker brown. Bolivia.
- semirufa*. **D. (?) semirufa** Drc. ♂. Head, collar, tegulae, thorax and abdomen yellow; antennae and legs black. Forewing red, costal margin and distal margin greenish yellow; hindwing yellow, margined with black from the apex to the anal angle; fringe yellow. Both wings beneath yellow, broadly margined with black. 38 mm. Colombia, Rio San Juan, Chaco (G. M. PALMER).
- variegata*. **D. (?) variegata** Jones. ♂ palpi ochreous; head and antennae grey; legs ochreous, tarsi white, their last joints black; tegulae and patagia brown. Abdomen above golden yellow, pale ochreous beneath. Forewing yellow, distal half suffused with brown, very dark at the margin, and a curved undulate antemedian line. A brown spot in the cell. An orange, black-edged line is followed on the discocellular veins by a yellow area. A large macula and a small one at the apex. Hindwing orange. Marginal area and distal margin broadly black. Forewing beneath yellow, distal half with 2 yellow spots at the apex; hindwing yellow, the marginal area broadly yellow. Expanse: 23 mm. Castro, Paraná, Brazil.
- nigrella*. **D. nigrella** Dgn. Wings rounded as in *abrasa*. Forewing divided by two folds, the first before vein 6, the second on vein 7; all the veins originate from the cell separately; 4 and 5 nearing each other, 6—9 at equal distances from each other, 10 somewhat more remote, 11 from the cell. Hindwing: vein 8 free. Frons greyish, head and thorax blackish. Abdomen above blackish, the segments finely bordered with white; ventrum and coxae white. All the wings blackish; hindwing beneath growing paler on half of the abdominalis. Fringe of the same colour; somewhat whitish at the anal angle. 1 ♂, French Guiana.

2. Genus: **Zadalcera** Dyar.

Structures as in *Dalcera*, but vein 11 arises with veins 9 and 10 on a short stalk, whilst 9 and 10 are long-stalked. Type of the genus: *Zad. fumata* Schs.

- fumata*. **Z. fumata** Schs. Palpi and head orange. Collar whitish; thorax and abdomen orange. Forewing above light pinkish yellow, palest along the costa; an oblique black stripe at the end of the cell, below this stripe and from near the base of the subcostal vein almost to the middle of the distal margin there is an intense smoky black shadow from which a similar, though smaller shadow extends to the inner margin. Hindwing light yellow, orange along the inner margin; wings beneath orange, the forewing with a black base of the costa and a black macula at the end of the cell. 31 mm. Castro, Parana.
- arhathdota*. **Z. arhathdota** Dyar. Forewing "greasy" yellow, the costal margin and fringe without any light pink colouring. Hindwing orange. Expanse: 50 mm. Colouring otherwise very similar to that of *Dalcera abrasa*, but the wings are less oval, without a produced apex, but of a more normal shape, and the colouring is less intense. 1 ♀ Rio de Janeiro, Brazil.
- munica*. **Z. munica** Dyar. Similar to *fumata*, but vein 6 much nearer to the lower cell-angle. Discal transverse streak long and narrow. A median grey shadow to the margin is broadly expanded. Expanse: 31 mm. San Bernardino, Paraguay (K. FIEBRIG).
- dierrhoea*. **Z. dierrhoea** Dyar. Similar to *arhathdota*, but smaller. Vein 6 arises above the end of the discal vein instead of forming the continuation of it. Expanse: 35 mm. San Bernardino, Paraguay.

3. Genus: **Dalcerina** Dyar.

Antennae short, bipectinate, with an apical tuft of scales. Head projecting, eyes large. Palpi porrect, thin, projecting beyond the frons by half their length, not reaching the vertex. Legs slender, hind tibia only with a terminal spur, third joint tiny. Costal margin of costa straight, rounded at the apex. Vein 1 forked at the base, not ramified. 1 c present; vein 2 from the centre of the cell; 4 and 5 on a short stalk; cell closed by a widely angled fork of the discal vein; 6 midway between 5 and discal veins 7 and 8 on a long stalk below the upper cell-angle; 9 and 10 on a long stalk as in *Dalcera*, but 11 with 9 and 10 exactly as long; 12 from the base. Hindwing with 3 interior veins, 2 from the centre of the cell; 3 and 4 arise close next to each other; 5 from the lower part of the cross-vein; discal vein as on the forewing; 6 and 7 very far off from each other, parallel. 8 at the end of the cell very near to 8, but separated from it or only connected with it by traces of an anastomosis towards the base, where the vein is rounded towards the costal margin.

D. tijucana Schs. Forewing yellowish white, finely reddish along the distal and interior margins and through the centre of the wing; a black oblique line at the end of the cell and a black shadow along the media. Hindwing light yellow. Head orange, collar yellow, thorax light pink and the abdomen dorsally yellow, orange beneath. Wings beneath yellow, with a small black spot at the end of the cell on the forewing. 35 mm. Tijuca, Rio de Janeiro.

4. Genus: **Acraga** Wkr.

Body slender, proboscis very short, palpi thin, very short. 3rd joint very small. Antennae with very short pectinations. Legs thin, clothed with long hair, posterior tibia with 4 long spurs. Wings broad. Forewing: vein 3 is twice as far away from 2 as 2 is from 1, 4 half as far away from 3 as 3 is from 2. Hindwings projecting very far beyond the abdomen.

A. moorei Dyar (= *ochracea* Mr. nom. praecoc.) (168 d) is easily discernible by the dark-scaled veins. Ground-colour intensely ochreous yellow. ♂ 34, ♀ 44 mm. Brazil.

A. coa Schs. (168 d). Orange, all the veins of the forewing with yellow lines, more distinctly so in the ♂ than in the ♀. ♂ 33, ♀ 44 mm. Coatepec, Jalapa, Mexico. Orizaba; Honduras.

A. conda Dyar (168 d) was described as a variation of the following *ochracea* from which, however, it differs in the different kind of the ground-colour, the orange colouring seems to be spread across a yellow ground and is more intense at the inner margin. Guiana.

A. ochracea Wkr. Antennae not longer than the thorax, with very short pectinations. Wings reddish yellow. Mexico, Tierra Colorado, Costa Rica. Irazu 6000—7000 ft. (ROGERS), Ecuador. South Eastern Brazil, Rio de Janeiro.

A. meridensis Dgn. 22 mm. Palpi, head, antennae, body, legs, fringes and wings yellowish orange, the wings with long hairs at the interior margin and especially at the abdominal margin. Merida, Venezuela. 2 ♂♂. It is very closely allied with *ochracea* Wkr., but more orange.

A. canaquitam Dyar. ♂ of a glaring reddish brown, the veins of the forewing paler. Expanse: 38 mm. Of the shape of *coa* and *moribunda*, the veins with still more distinct pale lines, but of a darker, more uniform ground-colour. It may be that the forms mentioned will prove to be variations of one species. Pao Obispo, Mexico, December 1924.

A. ciliata Wkr. Pale red-brown. Body and legs beneath whitish. Antennae whitish, with brownish yellow scales. Forewing with a rusty red macula at the end of the discal area. Interior margin and the end of the cell distinctly marked brown. Jamaica.

A. infusa Dyar (168 d). Head and abdomen of a deep yellow. Thorax orange, forewing deep yellow. The margins and a stripe along the median vein and vein 4 orange. Hindwing deep yellow, slightly shaded with orange at the anal angle. 19 mm. St. Laurent, Maroni River, French Guiana.

A. melinda Drc. Forewing and hindwing uniformly yellowish orange, the forewing somewhat darker at the inner margin; beneath as above; head, antennae, thorax, abdomen and legs yellowish orange. 50 mm. Panama, Chiriqui.

A. angulifera Dyar. Body and wings pale lemon-coloured. Costal margin of forewing palest. Forewing: a dark brown, inwardly flawed line at the end of the cell, a subterminal brownish shadow below vein 7, bent inwards towards vein 2, then straight to the interior margin. Hindwing with a brown line at the anal angle. 21 mm. St. Jean, Maroni River, French Guiana.

A. leberna Drc. (168 e). Forewing creamy white with a broad reddish brown submarginal band extending from the apex to the anal angle; a small reddish brown spot at the end of the cell. Hindwing creamy white, with reddish brown dots at the anal angle. Wings beneath yellowish white without any marking. Head, thorax, abdomen, antennae and legs reddish brown. Ecuador, Sarayacu.

- arcitera.* **A. arcifera** Dyar is very closely allied with *leberna*, but the colouring is distinctly yellow instead of creamy white. French Guiana.
- flava.* **A. flava** Wkr. (= *sulphurea* Burm.) (168 e). Golden yellow. Antennae moderately pectinated, slightly tufted at the tips. Rio de Janeiro. French Guiana.
- cosmia.* **A. cosmia** Dgn. 30 mm. Palpi and coxae white mixed with yellow; head and thorax white; abdomen yellow, band whitish. Legs white with a few brown hairs. Wings white; forewing above slightly suffused with brown, sometimes hardly visible, extending from the base along the interior margin on the first half, then along vein 2 which it follows as far as close to the margin, rising subterminally to vein 5, above which it bends round and extends to vein 8 where it vanishes. A terminal brown streak at the apex between veins 8 and 9; the discocellulars brownish like the distal end of veins 2—5, too; a brown marginal edge of the anal angle at vein 5; fringe white with a few brown hairs near the anal angle and at the apex. Hindwing above and fringe white, dusted brown at the anal angle. Wings beneath and fringe white. San Antonio, near Cali, Colombia, 2000 m. 1 ♂, April 1909 (FASSEL). — var. **boliviana** Hopp. The Berlin Museum contains a specimen from Bolivia differing from the type in the discal parts of the forewings not being brownish, but the whole forewings being feebly yellowish white in contrast with the white hindwings. The brown marking is only distinct at the interior margin. Chest with yellowish brown spots.
- isotheca.* **A. isotheca** Dgn. (168 f). White and yellow, feet white, the first pair almost entirely covered with yellow scales; palpi yellow, with whitish tips. Antennae, head and body above yellow. Collar and thorax yellow mingled with white scales; ventrum partly whitish. Wings white. Forewing above suffused with yellow, especially the interior region except the extreme base as far as vein 1 c, then postmedianly on vein 2 and behind the interior half of the cellular vein 3 to 5. The suffusion vanishes and is only visible subterminally on veins 6, 7 and 8. White marginal dots of the ground-colour are situate between veins 2 and 5, uniformly touching the corresponding fringes. Margin and fringe from vein 5 to the apex white except a yellow apical spot above vein 8. Margin and fringe of hindwing correspondingly spotted yellow from the anal angle almost to vein 5; spot beneath small. Forewing beneath white with faint traces of the apical spot and a few yellow scales on the fringes. Expanse of wings: 25 mm. Lim, Panama; 2 ♂♂ (FASSEL).
- umbrifera.* **A. umbrifera** Dyar. Body above light brown, beneath white. Collar speckled white. Forewing: markings lighter. A dot at the end of the cell; with a broad postmedian shadow extending as far as the fringe between veins 3 and 5; a narrow shadow along the interior margin as far as the postmedian vein. Hindwing with a pale brown shadow at the anal angle, extending to the fringe. 22 mm. St. Jean, Maroni River, French Guiana.
- ferruginea.* **A. ferruginea** Hopp. The ♀ is rusty red without any marking, forewing somewhat darker at the interior margin; antennae, head and legs brownish ochreous, abdomen rusty red. Expanse: 32 mm. Pachitea, Peru.
- caretta.* **A. caretta** Schs. (168 a). White; forewing with a chocolate brown shadowy submarginal band which is intense at the anal angle, gradually vanishing and altogether absent at the interior margin. The discal cross-vein and the origin of veins 2 and 3 finely marked with brown. 1 ♂, Misantea, Mexico, June 1909 (R. MÜLLER). 1 ♀ Chiriquito, Panama (W. SCHAUS).
- obscura.* **A. obscura** Schs. Dark golden brown. Costal margin of hindwing somewhat paler. Expanse: 22 mm. São Paulo, Brazil.
- hamata.* **A. hamata** Schs. (168 a). Forewing somewhat falciform, slightly produced below vein 4 and rounded. Hindwing bent inwards below the apex, the anal angle produced. Antennae brownish greyish yellow. Head and thorax deep yellow. Hindwing pale yellow. Wings of a glaring yellow. Costal margin of hindwing whitish. Expanse: 28 mm. Juan Vinas. June; Tuis. May.
- elvira.* **A. elvira** Dogn. ♂ 20—21 mm. Forewing above black; interior margin interrupted by white in the centre, dusted with yellow outside. Hindwing above white, superficially dusted, with a black, rather thin marginal line; fringe black with a few pale tiny hairs. Forewing beneath black suffused with white in the centre and at the interior margin. Hindwing beneath as above, but the black margin reduced in the apical region. Fringe of hindwing whitish. Body above black with a few tiny white hairs; body beneath and legs white. ♀ 25 mm. Forewing with a very broad black costal-marginal edge, a thin marginal edge from the base to the interior margin, the other parts of the wing yellow; hindwing with a broad yellow central band blackening the base and the whole surface of the wing as far as beyond the middle of the costal and abdominal margins, finally narrowing down between the broad black marginal bands, at the apex between veins 4 and 5. 1 ♂, July 20th 1908, 1600 m; 1 ♀, August 24th 1908, 1800 m, Colombia.
- mariala.* **A. mariala** Dogn. 32 mm. Wings longer, palpi, head, antennae, thorax, forelegs, forewing beneath and fringe orange; hindwing, its fringe, and all the wings beneath of the same colouring, but paler. The wings are covered with tiny fine hairs, less so beneath and on the hindwing. Bogota, Colombia, 1 ♀, July 8 th 1919.

A. moribunda Schs. Antennae yellowish ochreous. Collar, thorax and the base of the abdomen paler, *moribunda*, the veins yellowish ochreous like the hindwing. Expanse: 33 mm. Volcán de Santa Maria, Guatemala.

A. perbrunnea Dyar. Dark purple; hindwing evidently of the same colour, although it is sorely damaged *perbrunnea*, in the type. Expanse: 25 mm. A ♂ from Oxapampa, 2000 m. (Coll. DOGNIN.)

5. Genus: **Dalcerides** Neum & Dyar.

Head very small, with large eyes, palpi thin. antennae very short, scarcely as long as the thorax, with fine bipectinations. Vein 1 of forewing separate, not ramified, 1 a present, the median vein H-shaped. vein 2 arises behind the middle of the cell, veins 3—5 close together. Cell broad, closed, 6 arises from the middle of the retracted upper half of the cross-vein; accessory cell small and rounded, 7—8 stalked from its pointed end; 9 from the same spot; 10 evidently absent, 11 from the apex of the accessory cell apparently connected with 12 which is separated from the base. Hindwing with two interior veins; veins 2—6 as on the forewing; 7 forms the continuation of the subcostal vein, 8 from the subcostal vein from the centre of the cell to the end of the cell, not divergent. A false discal vein extends to the angulation of the cross-vein between veins 5 and 6. Genotype: *D. ingenita* Edw.

D. ingenita Edw. (168 a). Forewing deep yellow, somewhat orange, but not very light. Forewing of *ingenita*, a somewhat darker colouring. Thorax, abdomen and legs of the same colour. Rather paler beneath. Distinct markings not present. From Arizona.

D. bicolor Schs. ♀: head, thorax, legs, and abdomen beneath reddish orange. Abdomen above blackish *bicolor*, brown. Forewing reddish orange, the veins somewhat darker. Hindwing black, scantily scaled. Expanse: 28 mm. Vollano Poas (Costa Rica), May.

6. Genus: **Anacraga** Dyar.

Antennae short, bipectinate, palpi thin, extending to the centre of the frons. Forewing with separate 2nd and 5th veins; 6 near the upper angle of the cell, a large accessory cell; 7 and 8 on a short stalk, 9 and 10 almost coalescent, likewise from the apex, 11 from the apex of the accessory cell, near the costa and parallel to the base of the subcostal vein. Hindwing elongated, triangular; veins 2 to 5 equidistant from each other. 6 and 7 separated and parallel; 8 connected with the subcostal vein at the exterior half of the cell, at the base separated from the latter and angled. Genotype: *A. citrina* Schs.

A. dulciola Dyar (168 f). Forewing brown; a yellow spot at the base extends to the centre of the interior *dulciola*, margin. Hindwing orange, shaded with brown at the fringes. Expanse of wings: 11 mm. Type from La Chorrera. May 1912 (BUSCK); another specimen from Porto Bello, December 1912 (G. F. CLEVELAND).

A. rebella Schs. Similarly coloured as *A. geos*, but much smaller, and the yellow colour not so bright; *rebella*, neuration different, since the centre of the cell is greatly retracted, whereby the accessory cell and the lower angle seem to be protracted, whereas in *geos* the end of the cell is not so retracted, but almost straight. Quite lemon-coloured with a slight orange tinge. Hindwing somewhat paler than the forewing and somewhat transparent. Expanse: 13 mm. Banana River, Costa Rica, March 1907.

A. citrina Schs. The whole lepidopteron is completely loamy yellow. Expanse: 17 mm. Type found *citrina*, in Trinidad.

A. citrinopsis Dyar is coloured like *citrina* Schs., but considerably larger. The ♂ has an expanse of 25 mm. *citrinopsis*. Only the ♂ is known so far. ♂ type from Callao, Peru (Mrs. M. J. PUSEY).

A. phileterea Schs. ♂ body orange. Forewing orange, darkest at the interior margin. Hindwing orange, *phileterea*, with a broad whitish yellow costal margin. Under surface paler. Expanse: 22 mm. Sixola, La Florida (Costa Rica).

A. sofia Dyar (168 a). Forewing pale cream-coloured: a brown subbasal clouding in the submedian fold; *sofia*, a faint brown clouding extends across the centre of the wing and subterminally; discal dot round, dark brown. Hindwing whitish warming into cream-colour along the interior margin. Expanse: 22 mm. Cuernavaca, Mexico. August 1906 (W. SCHAUS).

A. sororcula Dyar. Similar to *sofia* Dyar, smaller, most of the markings of the wings faint or rudimentary except the discal spot. Expanse: ♂ 12 mm, ♀ 16—17 mm; 4 ♀♀, 2 ♂♂ from Cayuga, May till October, and Misantla, Mexico. September 1910 (R. MÜLLER).

A. geos Schs. Lemon-coloured; the frons slightly grey, the interior margin of the forewing somewhat *geos*, darker; costal margin of hindwing slightly whitish. Expanse: 18 mm. Guapiles (Costa Rica).

A. ria Dyar (168 b). Entirely ochreous. Expanse: 18 mm. 1 ♂, Rio de Janeiro, Brazil (SCHAUS). It *ria*, may be the genuine *D. ochracea* Wkr., in which case this name would have to be cancelled as synonymous.

mesoa. **A. mesoa** *Drc.* (168 b). Forewing chrome yellow, the centre of the forewing from the base almost to the distal margin lead-coloured, hindwing uniformly chrome yellow; head, thorax and abdomen yellow; legs brownish yellow; both wings beneath uniformly pale yellow; the darker colour on the forewing hardly visible. Panama, Bugaba, 800—1500 ft., Volcan de Chiriqui (RIBBE in the Coll. STAUDINGER).

albescens. **A. albescens** *Hopp.* ♂ 16—17 mm. Completely white with a faint orange tinge. Forewing especially on the veins without a streaky lustre. Hindwing with long white small hairs at the abdominal margin. Venezuela: Maracay (P. VOGEL). 2 ♂♂. Type in Coll. HOPP.

luteola. **A. luteola** *Hopp.* ♂ forewing golden yellow, half of the inner margin and the costal margin yellowish ochreous. Hindwing somewhat paler, but darker yellow at the anal angle. Both wings beneath paler. Body light ochreous, head, antennae, palpi and legs yellowish. 22 mm. Para Brazil. (SIEBER.)

nana. **A. nana** *Dogn.* 17 mm. Antennae, head, body and forewing above golden yellow, forewing partly with rough scales, hindwing beneath of a bright lemon-colour. ♂, São Paulo, Brazil.

ingenescens. **A. ingenescens** *Dyar.* Forewing dull golden yellow; colour that of *ria* *Dyar* which DYAR presumes to be synonymous with *luteola* *Hopp* (Journal of the Wash. Ac. of Soc. 17, 1927, p. 557); hindwing pale yellow, more golden at the margin. Expanse of ♀: 32 mm. 1 ♀ known from Madeira, Venezuela. (Coll. DOGNIN.)

phasma. **A. phasma** *Dyar.* White, with faintly yellowish clouded markings in the lower halves of the wings; without a discal spot. Expanse of ♀: 17 mm. 1 ♀ known from Sinaloa, Mexico. (A. KUSCHE.)

7. Genus: **Acragopsis** *Dyar.*

Antennae short, bipectinate, palpi thin and erected up to the centre of the frons. Forewing: veins 2—5 separated, the upper part of the cell retracted to the base, vein 6 from the upper angle of the cell, 7—10 stalked from the same place, 9 and 10 coalescent, a small convex accessory cell from near the base to the end of the discal cell, vein 11 arises from its anterior part. Hindwing: veins 2—5 likewise separated, 6 and 7 separated and parallel; 8 connected with the subcostal vein at the exterior part of the cell, free and curved at the base. Genotype: *A. flavetta* *Schs.*

radians. **A. radians** *Hopp* (168 b). ♂ 14 mm. Forewing yellow, slightly brownish, with a silky lustre, with deepened cross-veins, long-fringed. Hindwing whitish yellow, fringes and abdominal margin yellow. Both wings beneath cream-coloured. Body and appendages pale brownish. ♀ 17 mm. Forewing paler at the base. Hindwing whitish yellow. Sa. Catharina, 2 ♂♂, Santos, São Paulo, another specimen.

flavetta. **A. flavetta** *Dyar.* Body ochreous. Wings lemon-coloured, the veins of the forewing slightly darker. Expanse: 16 mm. San Jean, Maroni River, French Guiana.

chirma. **A. chirma** *Schs.* (168 b). ♂ body and forewing golden yellow; hindwing paler yellow. Expanse: 13 mm. Cayuga, Guatemala.

8. Genus: **Minonoa** *Dyar.*

Antennae short, bipectinate, palpi short, proboscis absent. Veins 2—5 of forewing at equal distances; 6 arises above the discal vein, 7 and 8 as well as 9 and 10 coalescent, 11 near the end of the cell. Veins 3 and 4 of the hindwing nearing each other at the origin, 6 arises above the discal vein, separated from vein 7 and parallel to it, 8 anastomoses with the subcostal vein at about the exterior third of the cell. Genotype: *M. perbella* *Schs.* According to DYAR who, however, has examined neither of these species *D. variegata* *Jones* and *A. elvira* *Dogn.* belong to this place here (loc. cit.).

perbella. **M. perbella** *Schs.* (168 b). Body orange above, paler beneath. Forewing: basal half yellow, partly suffused with brown, with a brown antemedian line. Exterior half dark brown, suffused with orange behind the cell. A yellow dot at the apex; a double darker marginal line is divided by a few orange spots. Hindwing orange; the distal margin broadly shaded with black. Expanse: 21 mm. Petropolis, Brazil.

pachitea. **M. pachitea** *Hopp.* ♂ apical and basal areas blackish brown, a broad orange band between them, forming in the middle a projection into the apical area and widened inside. Hindwing black. Antennae, head, thorax and abdomen blackish brown, legs whitish. Expanse: 19 mm. Pachitea, Peru.

9. Genus: **Minacragides** *Dyar.*

Forewing without an accessory cell; vein 11 stalked with 9, 10 absent; 6 arises above the discal vein, 7 and 8 coalescent.

arnacis. **A. arnacis** *Dyar.* Completely milky white; the only ♂ according to which the genus and species was described, is partly worn, but according to DYAR no traces of markings could be found. ♂ type from Hoorie, British Guiana (C. W. BEEBE).

10. Genus: **Minacraga** Dyar.

Antennae short, bipectinate, with tufts of scales at the tips; palpi oblique as far as the middle of the frons; forewing with a prominent angle, the fringe forming a lobe at the tornus. long spatulate scales. Forewing with equidistant veins 2 and 3; 4 and 5 from a place at the lower angle of the cell, 6 from above the discal vein, 7 and 8 on a long stalk; 9, 10 and 11 stalked. Hindwing: vein 4 from the lower angle of the cell, 5 far above it, 6 and 7 separated from each other and parallel, 8 extends near the subcostal vein to the end of the cell. Genotype: *M. disconitens* Dyar.

M. disconitens Dyar. Palpi dark brown with pale brown tips; antennae dark brown with black. Thorax *disconitens*. light brown. Tegulae dark violettish brown. Forewing pale, metallic dark brown, except at the margins which are pale. A broad dark brown stripe at the base of the interior margin; a black dot at the end of the cell. A subterminal undulating line followed by metallic dark brown spots between veins 3 and 5, these spots followed by a dark brown marginal shadow; the lobes on the interior margin light brown. Hindwing yellowish dark brown, the distal margin shaded with blackish brown, especially towards the anal angle. Expanse: 30 mm. Maroni River. French Guiana.

M. indiscata Dyar (168 e) resembles *disconitens*. Wings without silvery scales, but suffused with pale *indiscata*. brown, while the marginal markings are feeble. Discal dot present. Hindwing pale brownish and with a faint dark shading below the centre of the distal margin. Expanse: 27 mm. French Guiana.

M. argentata Hopp. Discal and inner-marginal areas of a metal lustre with a vertical furrow of pressed *argentata*. scales, bordered outside by a thin brownish ochreous line from the costa to the inner margin. The line vanishes inwards and is convex outwards. A diffuse brownish ochreous stripe at the distal margin is halved by a dot and terminates into the centre of the distal margin the fringe of which is brownish. A short dark brown stripe at the base of the inner margin the lobe of which is lighter and contains 2 tiny dots. A faint discal spot is present. Hindwing brownish at the distal margin. Both wings beneath whitish, the distal margins with the markings of above. Palpi brown outside, white inside. Head, body and legs light yellowish brown. Thorax and abdomen dorsally suffused with brownish. Antennae white with black apical tufts. Expanse: 23 mm. Pachitea, Peru.

M. aënea Hopp exhibits a light bronze lustre, darker towards the distal margins. Forewing strewn *aënea*. with single black dots, the centre of the distal margin blackened. 2 or 3 light lustrous subterminal spots between veins 2 and 4, a small black spot at the end of the cell. Hindwing with a small black spot in the centre of the distal margin, with a fine light, dark-edged line before it extending to the anal angle. Wings beneath creamy with a less intense lustre. Centre and distal margins darker; hindwing with a few scattered small black scales. Chest bronze-coloured. Abdomen silvery. Antennae light, pinnate, with tufts of black scales. ♂ from Sa. Catharina, Southern Brazil; expanse of ♀: 40 mm. Joinville, Sa. Catharina.

11. Genus: **Paraeraga** Dyar.

Antennae short, bipectinate, without tufts of scales; palpi thin, reaching the centre of the frons. Veins 2—5 separated, 6 arises above the end of the discal vein, 7 and 8, 9 and 10 anastomosing, 7 and 9 stalked, 11 arises near the end of the cell. Hindwing long oval, veins 2—5 separated, 6 and 7 separated, parallel, 8 extends near the subcostal vein to the end of the cell. Genotype: *P. innocens* Schs.

P. innocens Dyar. Body brownish yellowish white, wings white. Forewing scantily suffused with dark *innocens*. brown scales in the cell on the interior margin, in the exterior half of the costal margin and at the distal margin. Costa pale dark brown; a black dot right in front of the centre of the inner margin; a curved black line extends from the centre of the costa to the end of the cell, followed by a dark postmedian line which is bent towards vein 3, then undulate to the inner margin; distal margin clouded with light brown below vein 6; with a few dark marginal dots. Expanse: 18 mm. St. Laurent, Maroni River, French Guiana.

P. amianta Dyar. Forewing yellowish ochreous; costa narrowly white at the apex and distal margin. *amianta*. A lustrous silvery area in the centre of the wing, from above vein 1 to the lower part of the cell, a brown line from the origin of vein 2 almost reaches the costa and then returns across the discal vein, terminating on vein 1 above the extended anal angle, enclosing an irregular rusty brown marking in the cell. A tiny black dot on vein 1 in its basal third; a marginal series of similar dots at the ends of the veins, distinct only on veins 2—4 and subapically. Forewing white with an ochreous patch, except at the margin. Expanse: 24 mm. 1 ♂, Hoorie, British Guiana (C. W. BEEBE).

P. argentea Schs. (168 b). ♀ head and thorax quite whitish yellow. Metathorax and abdomen silvery. *argentea*. Forewing silvery yellow, except a large silvery white irregularly oval stripe extending from the posterior margin to the inner margin near the tornus and bordered with ochreous or dark brown scales; dark marginal dots on the veins, the largest at the apex of vein 7. Hindwing white, suffused with silvery scales. Under surface white. Expanse: 30 mm. Costa Rica.

- halophora*. **P. halophora** Dyar resembles *argentea*. Forewing white; with a slight rusty tint and dark suffusions. Costa somewhat more rusty. Distal margin with black dots on veins 3—8, those on 3 and 8 being larger; a black dot in the centre of vein 1. A narrower darker line at the upper cell-angle with a slight reddish shadow. A line from the upper cell-angle is strongly bent outward, reaching the tornus. Interior part of the discal line continued across the cell to the median vein; the area thus enclosed shows a silvery glimmer on the undulate surface and extends almost to the base below the median vein and above vein 1. Hindwing white with small black dots at the end of veins 2 and 3. Expanse: 24 mm. Pnablo Pasdo, Col. de Perene, Peru.
- necoda*. **P. necoda** Drc. ♂ head, antennae, collar and tegulae, thorax, abdomen and legs yellowish white. Forewing light fawn-coloured, darkest at the apex and distal margin; a reddish fawn-coloured spot at the cell-end, from which 2 faint brown lines extend almost to the anal angle; a tiny black dot in the centre of the inner margin. Hindwing light fawn-coloured, lightest at the base, fringes whitish. — ♀ very similar, but larger and almost entirely white. Expanse: ♂ $\frac{3}{4}$, ♀ $\frac{3}{10}$ incl. Colombia, Don Amo (DRUCE).
- canalicula*. **P. canalicula** Dogn. (168 b). Wings white, forewing with a yellowish glimmer. Forewing scantily strewn with ochre; a median brown dot on vein 1; 2 ochreous lines almost parallel, uniting in front at the exterior third of the costal margin; interior lines more straight, cutting the cell, extending across the origin of vein 3 to the posterior margin a little before the anal angle. Exterior line outwardly rounded, ending between 6 and 4 and at the anal angle; a few brown dots at the ends of the veins. Wings beneath, fringes, legs, and body white. Closely allied with *innocens*. La Oroya, Rio Inambari. Carabaya, South-Eastern Peru. Expanse: 20 mm.
- cyclophera*. **P. cyclophera** Dyar. Creamy white; forewing feebly shaded with brown. Lines connected with each other and remote from the anterior and posterior margins, forming an elliptical ring which is more pointed below than above. thin, brown; some groups of scales are in its upper part; a dot on vein 1 near the centre, and a marginal row of dots on the veins. Hindwing without spots. Expanse of wings: 20 mm. Type from Cabima. May 1911 (BUSCK).
- oxydata*. **P. oxydata** Hopp. ♂ forewing white, suffused with rusty red; a rust-coloured zone at the costal margin outside the cell, defined in a straight line towards the apex, vanishing, however, towards the base and forming a very indistinct band towards the anal angle. A faint dot at the fork of veins 7 and 9, a few faint dots also at the margin. Beneath white, feebly rusty at the costal margin. Hindwing, body and appendages white. Expanse: 15 mm. Teffé (Amazons).
- pulverina*. **P. pulverina** Schs. Antennae, head, thorax and legs yellowish white. Abdomen white, forewing whitish yellow, scantily suffused with fine dark brown scales; the suffusions form an oval spot on the distal part of the wing, the anterior part bent above the discocellular line, the posterior part narrower and not quite meeting the interior margin; a small brown antemedian spot on the submedian line. Hindwing white, wings white beneath. Costal margin of forewing whitish ochreous, suffused with brown. Expanse: 15 mm. Cayuga, Guatemala.

13. Genus: **Ca** Dyar.

Veins 8 and 10 of forewing absent; 9 and 10 on a long stalk or anastomosing. Veins 3 to 4 of the hindwing on a short stalk. 5 to 7 separated, 8 broadly united with the cell. Genotype: *Ca anastigma* Dyar.

- anastigma*. **Ca anastigma** Dyar. Forewing light yellow; an undulate dingy olive shadow extends across the interior third of the wing. The similar submarginal shadow irregular, badly defined, partly touching the margin. Discal dot small, round, black, situate upward towards the costa; 2 tiny black dots at the apex. Hindwing whitish with a faint yellowish tint. Expanse of wings: 11 mm. Type from the Trinidad River, March 1912 (BUSCK).

14. Genus: **Zikanyrops** Hopp.

Forewing with an accessory cell as in *Dalcerides*. Veins 8, 9 and 10 anastomosing. 2 from the centre of the cell-vein, 3 a little before the cell-angle, 4 from the latter, 5 a little before the media, 6 right behind it, 7 from the accessory cell, 9 likewise; 11 from the anterior edge of the accessory cell, 12 free. Hindwing: vein 2 from the last third of the cell, 3 and 4 from the cell-angle, almost somewhat stalked, 5 a little before 6 behind the media, 7 from the anterior cell-angle, 8 close beside it from the cell. Cell of forewing rather broad, divided by the media into two almost equal halves. Accessory cell small. Frons scarcely as broad as the eyes; palpi narrow, slightly upturned. The frenulum is without the retinaculum (see *Epipyropidae*).

- sparsa*. **Z. sparsa** Hopp. ♂ 15 mm. Creamy white. Forewing strewn with dark brown scales, especially between the apex and cell. Cell-crossvein and veins 5 and 6 basally with whitish hair. Costa beneath in the basal half dark brown. Palpi brownish. Brazil, Minas Geraës, Passa Quatro, November 26th 1917 (Zikán), 1 ♂.
- dubiosa*. **Z. dubiosa** Hopp. Accessory cell somewhat narrower and longer than in *sparsa* and not projecting half outward, but only representing a section of the anterior half of the cell. ♀ 22 mm. Head, legs, hindwing and

the inner-marginal area of the forewing pink, with a blackish hue on it, as in *D. tijucana* Schs. Hindwing with pink fringes. Bolivia: Cochabamba, Yunga del Espirito Santo (P. GERMAIN, 1888—89), 1 ♀.

Additions to *Dalcera* p. 1304.

D. canescens W. H. T. Tams (168 e). Antennal shaft covered with white white scales. The characteristic *canescens*. tufts of scales before the white tips are black; pectinations brown. Head with an orange vertex, greyish brown. striped black. Frons suffused with greyish yellow. Thorax from light to warm fawn-colour. Tegulae whitish, greyish brown at the base. Abdomen above and beneath and the chest orange. Legs with femora inside orange golden greyish brown or greyish brownish black suffused with orange and white inside, outside only white. tarsi greyish brownish black, the 1st to 3rd joints with white tips. Middle leg with an orange femur, tibia orange beneath, greyish brown suffused with white beneath; tarsi greyish brown with white-tipped 1st to 3rd joints. Hindlegs orange; tibiae and tarsi above with few greyish brown hair-scales, the last 4 joints of the tarsi greyish brown. Forewing reddish greyish brown with a fine reddish claret-coloured reflection; costa white, bordered with greyish brown of 4—6 mm width except at the base, and at the apex, where the border is mixed with the general colour of the wing; inner margin with a whitish fringe. Hindwing orange with a greyish brown margin of only 4 mm width, which is broadest on the vein M 1, from where it gradually narrows down towards the anal angle. Forewing beneath dull orange, leaving a terminal brown margin from the base to the junction of R 4 + 5; broader at the apex, narrower towards the tornus: costa bordered with a warm fawn colour; hindwing as above. Expanse: 46 mm. Yahmarmayo, 1200 ft., April 1912.

D. consanguinea Dyar. Forewing pale purple grey, shaded blackish outside; costal margin, interior *consan-* margin and distal margin narrowly pale yellow. Hindwing orange with a black narrow distal margin, less broad *guinea*. than $\frac{1}{4}$ of the length of the forewing. Expanse of ♂: 39—45 mm. Rio Tabajoz, Amazonas; Brazil; Porto Velho, Rio Madeira, Brazil. It may not be different from *D. semirufa* Drc.

Family: Epipyropidae.

By Dr. HERBERT SICK.

(See Vol. 10, page 721.)

The *Epipyropidae* are closely allied with the *Dalceridae*, but they have become specialized biologically to such a degree that they may be justly treated as a separate family. The life-habits of the larvae of these rare species are very peculiar. They live epiparasitically on *Hopmopterae* (*Psyllidae*, *Jassidae* etc.). WESTWOOD supplies a rather detailed account (1876) in Trans. Ent. Soc. London, p. 522. According to it, the larvae never hurt their hosts, but merely live in the wax-secretions. Thus it is a parasitism similar to that of the *Galleria*-species living in the wax of bee-hives, though the latter also occasionally attack the stock of young bees. In examining a *Phenax variegatus* Oliv. (a Homoptera) contained in the Berlin Museum I was able myself to ascertain the position of the pupa of an *Epipyropida* and I presume that the larva spins a thin membrane above itself in order to hold itself thereby in the wax. The larva itself, according to DYAR, is almost hemispherical, somewhat elliptic, flattened on the ventral side and very uniformly convex dorsally. The head is rather large and retractile. The number of thoracal legs is normal, but they are short and rudimentary. The abdominal legs are represented by elliptic hooks on segments 4 to 6, and one pair is distinct on the last segment. The segments are short, contracted and provided with a large number of secondary hairs. Tubercles are not to be distinguished. According to SCHWARZ, the larvae are covered with a wax-secretion. The colour of the larvae is greyish white. The imago is sexually dimorphous. The systematic position is not yet clear. They are surely closely allied with the *Dalceridae*, which is already proved by the fact that some *Epipyropidae* were described as *Dalceridae*. The latter are again allied with the *Limacodidae*, according to the shape of the larvae common to all the three families. KIRBY placed the *Epipyropidae* to the *Liparidae*, which is absolutely wrong, since beside other marks the *Epipyropidae* are without a tympanal organ which is developed in the *Liparidae*. SHARP is right in presuming a relationship to the *Limacodidae*. From these they differ in the absence of the tibial spurs and in the radius sector of the forewing, which proceeds from the anterior margin of the cell and defines a part in front in the cell. The cell is besides parted yet by a median vein. All the veins mostly arise from the cell and are sometimes stalked or also fused. Vein 8 of the hindwing anastomoses with the cell, 7 may arise separately from the base or also be absent. The oral membranes are rudimentary and only present in a biarticulate appendage provided with a hair-tuft. Ocelli and chaetosema absent, frenulum plain in both sexes. The species of this family sometimes propagate parthenogenetically (or rather in an agamic way), which is rarely the case in lepidoptera and, for instance, occurs in *Psychidae* (*Apterona helix* Sieb., Vol. 2, p. 364).

1. Genus: **Epipyrops** Westw.

Proboscis absent; palpi tiny, frons smooth, eyes large, antennae long, bidentate in both sexes; tibiae without spurs. Forewing with a slightly protracted apex, the margin uniformly bent, vein 3 arises in front before the cell-angle, 4 and 5 from the latter, 6 to 11 from the cell. Hindwing: vein 3 arises before the cell-angle, 5 above it, 6 below the upper cell-angle.

E. barberiana Dyar. Vein 1 of the forewing plain, 1 c present, extending far outward; veins 2 and 3 *barberiana*, equidistant, 4 and 5 rather closely together, 6 and 7 equidistant, 8 and 9 equidistant, arising from the longest part of the cell, 10 and 11 like 6 and 7, arising from the cell near the end, 12 freely from the base. Hindwing evidently with 3 interior veins, but that part of the wing of the type is altogether ruined; vein 2 from the centre of the cell, 3 separated, 4 and 5 near together though not so much as on the forewing; 6 and 7 separated. cell rounded, its upper vein feeble; vein 8 from the base, free. ♂ frenulum plain. Head and thorax appear to be as in *Epipyrops*; palpi very small, legs without visible spurs. Arizona and New Mexico.

cucullata.

E. cucullata C. Heinrich is a small blackish grey species hardly discernible from *barberiana* except by the genitals. Forewing and hindwing of the same colouring. Head and thorax somewhat darker. The tegumen of the ♂ genitals is enlarged and cucullate. Expanse: 10 mm. Type found in Port au Prince, Haiti.

2. Genus: **Epipomponia** Dyar.

Hindwing with 8 veins. 7 and 8 of the forewing separated: 8 of the hindwing connected with the subcostal vein by anastomosis.

multipunctatum.

E. multipunctatum Drc. (168 g) was described as *Cossus* (?) by Druce. Forewing deep black, ♂ densely striped with small blue spots; hindwing uniformly smoky black; both wings beneath lustrous brownish black. Costal margin of forewing densely speckled with blue spots; head, thorax and legs black. 32 mm. Forewing of ♀ metallic greenish blue, veins and numerous transverse streaks bluish black with a slight lustre on the upper surface of the forewing. Body somewhat more lustrous than the hindwing.

elongata.

E. elongata Jordan. The ♀ is oily bluish grey, bluish green scales along the costal margin of the forewing above and near the base form indistinct spots, a thin marginal line and part of the fringes likewise lustrous metallic, but more golden green. Frons as broad as both eyes, somewhat concave in the middle before the antennae which are more roughly scaled than in *multipunctatum*. The distal part of the antennae exhibits a comb of scales. 12 joints bipectinnate, the longest branches as long as three diameters of the shaft. Forewing almost three times as long as it is broad; 10 veins from the cell, radial veins 1 and 2 more separated than in *multipunctatum*. Hindwing likewise elongated, more than twice as long as it is broad. Expanse: about 31 mm.

3. Genus: **Protacraga** Hopp.

Originally regarded as a genus of the *Dalceridae* by HOPP who, however, later on recognized it to belong to the *Epipyropidae*, though the only species of the genus may belong to the *Epipomponia*. Median vein and that longitudinal vein which separates the accessory cell from the cell — it may be considered as a second media — very feeble. HOPP presumes the accessory cell to have been produced phylogenetically by an anastomosis of the basal parts of the second media and of the radius, not by the ramification of the radius. Veins 2 and 3 arise from the posterior edge of the cell, 4 and 5 nearing each other from the posterior cell-angle, 6 is the continuation of the 1st media, 7 arises from the cross-vein somewhat nearer to 6 than to 8, 8 shortly before the second media, 9 from the cross-vein of the accessory cell, nearer to 8 than to 10, 10 and 11 separated from the distal part of the anterior edge of the cell, 12 freely from the base, thickened at the bottom. Hindwing: 1 a, 1 c present, 2 and 3 from the posterior edge of the cell; 3 nearer to 4 than to 2, 4 and 5 from the posterior cell-angle, 6 shortly above the media, 7 is the prolongation of the anterior edge of the cell. Head small, correct. Legs thin, hind tibiae without spurs or only with very small spurs; antennae short, short in the ♀ but distinctly pinnate.

micans.

P. micans Hopp (168 g ♀). ♀ head, thorax, legs, abdomen and wings blackish brown with partly greenish lustrous scales; antennae black. Apex of forewing and fringes white with a number of bright green lustrous scales behind. Hindwing at the distal margin and anal margin with white fringes passing over into greenish towards the inner margin. Beneath as above, but the greenish reflection is less intense. Length of forewing: 17 mm. "Brazil" (BESCKE).

4. Genus: **Anopyrops** Jordan.

♂ ♀ frons one third as broad in the middle as both eyes together (seen from in front). In the proximal half of the ♀ forewing the costa is connected with the cell by an anastomosis in a distal direction from the cell; in the ♂ the anastomosis is rudimentary.

corticina.

A. corticina Jordan. ♂ antennae with 12 bipectinate joints, the longest tufts as long as 6 diameters of the shaft. Body and wings dark greyish brown. Frons, antennae, head beneath and body beneath, interior margin of hindwing above, base and anal margin of forewing beneath and the hindwing beneath except the costal area white. Thorax above mixed with grey. Forewing very broad, round, with the full number of veins, subcostal vein 2 of forewing nearer to subcostal vein 1 than to 3; a feeble subbasal fold on the hindwing connects the costal vein with the cell. ♀ much larger than ♂; distal margin of forewing more convex, hindwing more rounded, anastomosis between the costa and cell of the forewing well developed, either subbasal or near the centre of the cell. Longest tufts of the antennae as long as 3 diameters of the shaft. Dark brown; forewing above with numerous small white dots, inner margin on both wings suffused with white. Subcostal vein 2 of the forewing nearer to subcostal vein 3 than 1. Length of forewing: ♂ 8.5 mm. ♀ 13.5 mm. French Guiana: St. Jean de Maroni. ♂ type. Surinam: Aroewarwa Creek, Maroewym Valley. May 1905. 2 ♀♀ (S. M. KLAGES).

5. Genus: **Oedonia** Kirby (Pseudopsyche Hy-Edws. nom. praecoc.)

The genotype *Oe. exigua* Hy. Edws. is said to correspond to *Epipomponia cucullata* and *barberiana*. But as I have no specimen of these species at hand, we quote EDWARD'S genus here, though its right to exist is doubtful. Antennae tufted, the bristles scanty, rather long, and forked at the tips. Thorax short, broadly clad with scales. Abdomen shorter than the hindwing and broad at the base, then suddenly tapering. Forewing very much protracted at the apex, broader than the hindwing which is rounded at the anal angle and protracted at the apex. Tibiae without spurs, but covered with rather long extended hair.

E. exigua H. Edws. was originally described as a *Psychida*, but FRANK MORTON JONES ascertained *exigua*, that it is an *Epipyropida*. Quite ore-black, the scales of the forewing with somewhat metallic dots. Expanse: 13 mm. San Francisco Mts., Arizona.

Alphabetical List

of the original descriptions of the American forms of *Epipyropidae*.

* signifies that the form is also figured at the place quoted.

Additions and Corrections.

The present volume being the most voluminous of the entire work, extensive additions and corrections must be out of the question. Mistakes may have crept in here and there, they were inevitable owing to the extent of the volume the publication of which was started already in 1906. Errata and other purely technical mistakes will be published at the end of the volume as usual.

P. 1010. **Oiozona geometrica** *Drt.* has proved to be a genuine Geometrid after the tympanal organ was examined. It must be cancelled here and will be quoted at the right place in Vol. 8.

P. 1144. **Psamathia ochriplaga** *Dgn.* (1913) is a synonym to **amanda** *Maass.* (1890) which has therefore the priority. (Lep. coll. during a trip through Colombia, Ecuador, Peru, Brazil, Argentina and Bolivia. By ALPHONS STÜBEL, Berlin 1890, p. 160.)

P. 1273. Before *Heterocoma*:

Schausiania ophthalmodes *M. Her.* (168 h) is similar to *S. gaudeator* *Schs.*, but discernible by a transverse band bordering on the terminal spot towards the base and expanding at the tornus. Head blackish brown, frons lighter between the eyes and the base of the antennae, brownish ochreous, slightly mixed with dark. The 2nd palpal joint 5 or 6 times as long as the 3rd. Thorax, patagia in front brown, the rest white. Dorsum with fine black dots, abdomen chocolate brown, distal margin of hindwing brownish bluish grey with a few transverse stripes of fine streaks. At the base there is a white spot as in *gaudeator*. Two indistinctly defined spots are situate at $\frac{1}{4}$, one below the costal margin and another spot below the posterior edge of the discal cell; two white spots at $\frac{1}{2}$, the first more towards the margin. The margin is bordered by a brownish ochreous, but proximally more reddish stripe between the 2nd radial vein and the 2nd cubitus. This marginal area contains a black marking extending towards the base as a band parallel to the red-brown border; from this band longitudinal stripes proceed then to the margin, which may be either interrupted or run along the distal margin and then back again. This eyelike marking of the marginal area may make the impression of a black spot containing ochreous spots. The black colour is reduced in the ♂, but always distinct in the basal part of the spot. The characteristic transverse band is situate between the rusty brown area and the other part. It does not reach the costal margin, is very thin subcostally, but widens towards the anal margin. Hindwing reddish chocolate brown, fringes more reddish, in the ♂ with few white spots. Forewing beneath lighter red-brown, the last two thirds of the costal margin whitish. The black spot of the terminal area shows through. Hindwing as above, sometimes with darker transverse striae. ♂ 25, ♀ 30 mm. ♀ type and a ♂ from Obidos (Brazil) in the Berlin Zoolog. Museum.

Sch. furfurens *M. Her.* (168 h). Body bluish grey, thorax with a broad velvety black longitudinal stripe widening in front and behind. Palpi chocolate brown, with some white hairs below. The 2nd palpal joint about $2\frac{1}{2}$ times as long as the 3rd. Antennae light yellowish brown. Forewing broad at the base, costal margin and anal margin almost parallel. Forewing creamy white, with blackish brown transverse striae. A black spot at the base and a comma-shaped streak between the anterior edge of the cell and analis are more prominent, just like a series of spots especially conspicuous beginning between analis and axillaris and with its 1st spot between the two veins removed somewhat distally in the centre of the wing. Below the apex at the distal margin there is a semicircular line extending from the apex to m 2 and from there between m 2 and m 3 parallel to them. From this arcuate line two feeble ramifications proceed into the centre of the circle. Close before the apex there is another blackish brown dot. Fringe brownish, lighter at the bottom, with fine white partition-lines. Hindwing white, brown dots at the ends of the veins are sometimes confluent. Forewing beneath brown, basal area and costal margin whitish, markings as above, but less distinct. Hindwing as above, but a brown spot at the end of the discal cell between m 1 and m 3. Length of forewing: 14 mm. Bogota, April 8th 1871 (NOLCKEN) 1 ♂. Type in the Berlin Zoolog. Museum.

P. 1273.

8a. Genus: **Allostylus** *M. Her.*

r 1 of the forewing arises from the anterior edge of the accessory cell, r 3 and r 4 are stalked, their stalk again shortly stalked from the apex of the accessory cell. r 5 arises in the middle between the stalk and

m 1 behind from the accessory cell; in the hindwing it is quite free, rr and m 1 are distinctly separated. ♂ antennae bipectinate to the tips. Genotype: *A. (Cossula) caerulescens* Schs.

P. 1174, to *Hypopta*:

H. selenophora *M. Her.* (168 g). Head and thorax yellowish brown, abdomen darker. Palpi yellowish brown, the 2nd joint long-haired, the 3rd joint much shorter than the 2nd. Wings rather narrow. Costal margin straight. r 1 arises before the cell, r 2 from the anterior angle of the areole, r 3 and r 4 from the posterior angle of the cell, r 5 before the cell, an and ax anastomose in one place. Forewing bluish grey, with brown markings, among them a striking crescentiform macula at the costa before the apex. Towards the base a browner almost triangular spot between the base of m and r 1. A transverse band in the basal area, its interior border indistinct and its exterior edge running convex to the inner margin, crossing an, bent basad at $\frac{2}{3}$ of ax and enclosing there a crescentiform white spot. Distally to it there is a round spot, between m 1 and m 2 there are two distinct black spots in the prolongation of the lower crescent. Wings partly with a bluish white hue, the brown markings edged with whitish. Both wings beneath lighter grey, the distal halves of the crescents are distinctly visible. Length of forewing: 12 mm. S. Rosa, Mendoza (Argentina). November 25th 1904. ♂ type in the Berlin Zoolog. Museum. It may be that a new genus will have to be established for this species and the other species of *Hypopta*, whose an and ax anastomose.

H. albicosta *M. Her.* (168 g). Head and thorax whitish grey, metathorax dark, abdomen dark grey, lighter behind. Antennae bipectinate (? because broken), palpi blackish brown. The 2nd joint long-haired beneath, 4 times as long as the 3rd. r 1 proceeds from the cell, r 2—5 and m 1 from the areole, m 2 is very distantly separated from m 1, an and ax anastomose towards the end. rr and m 1 on a long stalk, m 2 farther away from the stalk than ms. Forewing reddish greyish brown. Costa as far as r 1 and r 2 white, an indistinct brown subterminal transverse line, proximally to it a parallel stripe of a whitish hue. Hindwing light grey. All the wings beneath unicoloured grey, hindwings beneath lighter. Length of forewing: 10 mm. Mendoza, ♂ type in the Berlin Zoolog. Museum.

P. 1276, before *Pernambis*:

13a. Genus: **Anastomophleps** *M. Her.*

Allied to *Hypopta* *Hbn.* from which it differs in the anastomosis of r 1 and r 2. Forewing very narrow, r 1 from the discoidal cell, r 1 from the areole and anastomosing right behind its origin with r 1, but later on separated again. r 1—r 3 extend to the costal margin, r 4 and r 5 stalked, the stalk proceeds from the posterior angle of the areole (accessory cell). m 2 and m 3 near together, basal parts of m forked far before the beginning of the areole. Analis anastomosing at about $\frac{3}{4}$ with ax. Hindwing: sc quite free, rr and m 1 arise together from the upper cell-angle, m 2 and m 3 and cu 1 at almost equal distances from the posterior part of the cell. cu 2 far from the posterior angle. Only 1 species.

A. claosticha *M. Her.* (168 g). Body grey, abdomen somewhat lighter beneath, the 3rd palpal joint only $\frac{1}{4}$ of the 2nd. Antennae of half the length of the forewing, in the ♂ only shortly pectinated, almost serrate. Legs grey, middle tibia in front with two conspicuous black spots. Costal margin of forewing concave, ground-colour above grey, the first third with a transverse row of black spots cutting the discoidal cell, the last spot situate on the interior margin is removed towards the margin. In the middle between this row and the base there is a similar spot at the costa. Flocks and dots are distributed all over the surface of the wing. A pre-apical series of spots, the costal spot of which is the smallest. Hindwing whitish, dusted brown towards the apex and anal angle. Beneath as above, but indistinct. Hindwing beneath with 3 distinct spots below the convexity of the costal margin on sc. Length of forewing: 15 mm. Mendoza, Argentina. January 1905 (JENSEN-HAARUP). 1 ♂ in the Berlin Zoolog. Museum.

P. 1277, before *G. superquadra*:

Givira quadroides *M. Her.* (168 h) is allied to *E. quadra* (182 d), but the distal border of the large brown spot situate below the cell is not concave, but straight. The ground-colour is more unicoloured, loamy yellow here. Basal spot lighter, not so contrasting as in *quadra*, all the white places of *quadra* are loamy yellow. Basal spot lighter, not so brown as in *quadra*, hindwing darker than in *quadra*, without the spot at the end of the cell. All the wings beneath similar to *quadra*, but less distinct and contrasting. Length of forewing: 21 mm. Sa. Catharina, Brazil (1896), ♂ type in the Berlin Zoolog. Museum.

*) All these appended genera and species of the *Cossidae* have been described in: Deutsche Entomol. Zeitschr. "Iris", Vol. 37 (1923) on pp. 11—14.

stellifera Schaus (Adalgisa) 671.
stenoxantha Hering (Myonia) 504.
stenoxantha Hering (Pseudophaloë) 429.
stigmatiea Pfitzner (Dalaca tesselloides) 1296.
stibina Draudt (Roeselia) 238.
stramentalis Draudt (Ancistreta) 748.
striata Draudt (Goac. variabilis) 1021.
striata Draudt (Josiodes repleta) 270.
strigifera Hering (Eucyane) 436.
strigifera Seitz (Idalus rosea) 348.
studyi Hering (Pericopia) 438.
suavis Draudt (Disphragis daona) 970.
subalba Hering (Myonia) 506.
subalbieans Dyar (Sibine) 1110.
sublucana Draudt (Titya) 585.
submaxima Hering (Tithraustes) 514.
subtropicalis Dyar (Miacora) 1274.
subvanaria Strand (Cast. subvaria) 9.
suffusa Draudt (Josiodes variaria) 271.
suffumata Draudt (Autochloris) 52.
suffusa Draudt (Talara nigroplagiata) 250.
supposita Hering (Hyal. fenestra) 448.
suprema Hering (Pericopia) 438.
symphora Schaus (Anticla) 691.
syngenica Zuk. (Euryphrissa) 1246.
sypalettus Seitz (Automolis) 366.

taedia Draudt (Euglyphis) 605.
taeniata Draudt (Aclytia hoffmannsi) 157.
tamara Hering (Calodesma) 433.
tamara Hering (Josia) 527.
taminata Draudt (Eugl. thyatira) 601.
tamsi Draudt (Prorifrons) 569.
tanampaya Draudt (Rosema) 1056.
tauta Draudt (Euglyphis) 602.
pajoza Dyar (Cossula) 1271.
rasia Schaus (Anticla) 691.

tarchona Schaus (Stactherinia) 553.
tarudina Draudt (Tolype) 581.
tehuacana Draudt (Cerura) 946.
tehuacana Draudt (Goacampa variabilis) 1021.
tellinoides Hering (Pseudophaloë) 430.
temperata Draudt (Euglyphis) 613.
tendex Draudt (Hyles. darlingi) 757.
tenebrata Seitz (Aut. docis) 372.
tenebrata Hering (Isostola) 434.
tenuifascia Hering (Crocomela) 454.
tennistriga Draudt (Acthr. eliza) 115.
teratex Draudt (Hyles. thaumex) 753.
tergina Jord. (Harrisina) 28.
tessmanni Hering (Diopis) 522.
tessmanni Hering (Josia) 525.
tessmanni Hering (Pseudophaloë) 430.
texensis Draudt (Illice unifascia) 258.
thanates Hering (Tithraustes) 513.
thaumex Draudt (Hylesia) 753.
theobromana Draudt (Dirphia) 775.
thiuala Draudt (Apatelodes) 695.
thirmida Hering (Brachyglene) 524.
tineosphecia Zuk. (Synanthedon) 1232.
tirzaha Schaus (Trogophera) 653.
togata Draudt (Talara) 250.
torehana Schaus (Staetherinia) 553.
tosticrista Draudt (Euglyphis) 595.
transdueens Seitz (Robin. polyplagia) 344.
transiens Seitz (Azatr. fuliginosa) 379.
transita Hering (Actea) 524.
trapezina Draudt (Hemiceras) 1039.
trepida Draudt (Rhuda) 987.
triangulifera Hering (Josiomorpha) 432.
triangulum Draudt (Phyllopalpia) 939.
trinitatis Draudt (Chion. apicalis) 262.
tripunctata Strand (Cast. cochrus) 14.
tristicula Strand (Cast. amycus) 13.
trogon Draudt (Ixylasia) 209.
tumaeona Draudt (Disphragis) 977.
tupi Pfitzner (Hepialus) 1293.
turbida Hering (Eucyane) 436.
turbida Hering (Josia ilaire) 525.
turnina Schaus (Lacosoma) 660.
typhon Draudt (Betola) 948.
tyrannus Draudt (Eacles) 803.

umbratula Strand (Cast. pallasia) 10.
umbrosa Zuk. (Melittia) 1251.
undilinea Draudt (Hippia) 941.
undulata Hering (Tith. crymas) 513.
unicolor Hering (Polypt. fasciculosa) 530.
unifascia Hering (Pericopis) 443.
unifascia Hering (Stenoplastes) 518.
uniforis Draudt (Chrysocale) 205.
uniformis Hering (Scotuopsis) 508.
upanona Draudt (Dirphia) 768.
ursmara Schaus (Drucntia) 656.
ursula Hering (Myonia) 505.
usquieta Draudt (Gopha) 950.

valera Schaus (Lacosoma) 662.
valstana Schaus (Staetherinia) 553.
venata Jord. (Harrisina) 28.
ventriosa Draudt (Tolype) 582.
veranioides Hering (Pseudophaloë) 430.
vespertilio Draudt (Tolype) 582.
vialaetea Draudt (Hylesia) 759.
viemanda Schaus (Cicinnus) 648.
